Disclaimer and Legal Information

Document Number: 630813-034US

World Wide Web: <http://www.intel.com>

INFORMATION IN THIS DOCUMENT IS PROVIDED IN CONNECTION WITH INTEL® PRODUCTS. NO LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE, TO ANY INTELLECTUAL PROPERTY RIGHTS IS GRANTED BY THIS DOCUMENT. EXCEPT AS PROVIDED IN INTEL'S TERMS AND CONDITIONS OF SALE FOR SUCH PRODUCTS, INTEL ASSUMES NO LIABILITY WHATSOEVER, AND INTEL DISCLAIMS ANY EXPRESS OR IMPLIED WARRANTY, RELATING TO SALE AND/OR USE OF INTEL PRODUCTS INCLUDING LIABILITY OR WARRANTIES RELATING TO FITNESS FOR A PARTICULAR PURPOSE, MERCHANTABILITY, OR INFRINGEMENT OF ANY PATENT, COPYRIGHT OR OTHER INTELLECTUAL PROPERTY RIGHT.

UNLESS OTHERWISE AGREED IN WRITING BY INTEL, THE INTEL PRODUCTS ARE NOT DESIGNED NOR INTENDED FOR ANY APPLICATION IN WHICH THE FAILURE OF THE INTEL PRODUCT COULD CREATE A SITUATION WHERE PERSONAL INJURY OR DEATH MAY OCCUR.

Intel may make changes to specifications and product descriptions at any time, without notice. Designers must not rely on the absence or characteristics of any features or instructions marked "reserved" or "undefined." Intel reserves these for future definition and shall have no responsibility whatsoever for conflicts or incompatibilities arising from future changes to them. The information here is subject to change without notice. Do not finalize a design with this information.

The products described in this document may contain design defects or errors known as errata which may cause the product to deviate from published specifications. Current characterized errata are available on request.

Contact your local Intel sales office or your distributor to obtain the latest specifications and before placing your product order.

Copies of documents which have an order number and are referenced in this document, or other Intel literature, may be obtained by calling 1-800-548-4725, or by visiting Intel's Web Site.

Intel processor numbers are not a measure of performance. Processor numbers differentiate features within each processor family, not across different processor families. See http://www.intel.com/products/processor_number for details.

Legal Information.....	3
Chapter 1: Overview	
Introducing the Intel® Math Kernel Library.....	49
Getting Help and Support.....	49
What's New.....	50
Notational Conventions.....	51
Function Domains.....	52
BLAS Routines.....	53
Sparse BLAS Routines.....	54
LAPACK Routines.....	54
ScaLAPACK Routines.....	54
PBLAS Routines.....	55
Sparse Solver Routines.....	55
VML Functions.....	56
Statistical Functions.....	56
Fourier Transform Functions.....	56
Partial Differential Equations Support.....	56
Optimization Solver Routines.....	57
Support Functions.....	57
BLACS Routines.....	57
GMP Arithmetic Functions.....	58
Performance Enhancements.....	58
Parallelism.....	58

Chapter 2: BLAS and Sparse BLAS Routines

BLAS Routines.....	61
Routine Naming Conventions.....	61
Fortran 95 Interface Conventions.....	63
Matrix Storage Schemes.....	64
BLAS Level 1 Routines and Functions.....	65
?asum.....	66
?axpy.....	67
?copy.....	69
?dot.....	71
?sdot.....	72
?dotc.....	74
?dotu.....	75

Chapter 6: ScaLAPACK Routines

Overview.....	1979
Routine Naming Conventions.....	1980
Computational Routines.....	1982

Linear Equations.....	1982
Routines for Matrix Factorization.....	1983
p?getrf.....	1984
p?gbtrf.....	1985
p?dbtrf.....	1988
p?dttrf.....	1991
p?potrf.....	1993
p?pbtrf.....	1995
p?pttrf.....	1998
Routines for Solving Systems of Linear Equations.....	2000
p?getrs.....	2001
p?gbtrs.....	2003
p?dbtrs.....	2006
p?dttrs.....	2009
p?potrs.....	2012
p?pbtrs.....	2014
p?pttrs.....	2016
p?trtrs.....	2019
Routines for Estimating the Condition Number.....	2022
p?gecon.....	2022
p?pocon.....	2025
p?trcon.....	2028
Refining the Solution and Estimating Its Error.....	2031
p?gerfs.....	2032
p?porfs.....	2036
p?trrfs.....	2040
Routines for Matrix Inversion.....	2044
p?getri.....	2044
p?potri.....	2047
p?trtri.....	2048
Routines for Matrix Equilibration.....	2050
p?geequ.....	2050

p?poequ.....	2053
Orthogonal Factorizations.....	2055
p?geqrf.....	2056
p?geqpf.....	2059

Chapter 8: Sparse Solver Routines

PARDISO* - Parallel Direct Sparse Solver Interface.....	2495
pardiso.....	2496
Direct Sparse Solver (DSS) Interface Routines.....	2518
DSS Interface Description.....	2520
dss_create.....	2522
dss_define_structure.....	2523
dss_reorder.....	2525

dss_factor_real, dss_factor_complex.....	2527
dss_solve_real, dss_solve_complex.....	2528
dss_delete.....	2530
dss_statistics.....	2530
mkl_cvt_to_null_terminated_str.....	2534
Implementation Details.....	2535
Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS).....	2536
CG Interface Description.....	2541
FGMRES Interface Description.....	2547
dcg_init.....	2556
dcg_check.....	2557
dcg.....	2559
dcg_get.....	2561
dcgmrhs_init.....	2562
dcgmrhs_check.....	2563
dcgmrhs.....	2565
dcgmrhs_get.....	2567
dfgmres_init.....	2568
dfgmres_check.....	2570
dfgmres.....	2571
dfgmres_get.....	2574
Implementation Details.....	2575
Preconditioners based on Incomplete LU Factorization Technique...	2576
ILU0 and ILUT Preconditioners Interface Description.....	2579
dcsrilu0.....	2581
dcsrilut.....	2585
Calling Sparse Solver and Preconditioner Routines from C/C++.....	2590
Chapter 9: Vector Mathematical Functions	
Data Types and Accuracy Modes.....	2593
Function Naming Conventions.....	2594

Function Interfaces.....	2595
VML Mathematical Functions.....	2595
Pack Functions.....	2595
Unpack Functions.....	2596
Service Functions.....	2596
Input Parameters.....	2597
Output Parameters.....	2597
Vector Indexing Methods.....	2597
Error Diagnostics.....	2598
Vector Length Dependencies.....	2599
VML Mathematical Functions.....	2599
Special Value Notations.....	2601
Arithmetic Functions.....	2602
v?Add.....	2602
v?Sub.....	2605
v?Sqr.....	2607
v?Mul.....	2609
v?MulByConj.....	2612
v?Conj.....	2614
v?Abs.....	2616
v?Arg.....	2618
Power and Root Functions.....	2621
v?Inv.....	2621
v?Div.....	2623
v?Sqrt.....	2626
v?InvSqrt.....	2629
v?Cbrt.....	2631
v?InvCbrt.....	2632
v?Pow2o3.....	2634
v?Pow3o2.....	2636
v?Pow.....	2638
v?Powx.....	2643

v?Hypot.....	2646
Exponential and Logarithmic Functions.....	2648
v?Exp.....	2648
v?Expn1.....	2652
v?Ln.....	2654
v?Log10.....	2657
v?Log1p.....	2661
Trigonometric Functions.....	2663
v?Cos.....	2663
v?Sin.....	2665
v?SinCos.....	2668
v?CIS.....	2670
v?Tan.....	2672
v?Acos.....	2675
v?Asin.....	2678
v?Atan.....	2681
v?Atan2.....	2684
Hyperbolic Functions.....	2687
v?Cosh.....	2687
v?Sinh.....	2690
v?Tanh.....	2694
v?Acosh.....	2697
v?Asinh.....	2701
v?Atanh.....	2704
Special Functions.....	2707
v?Erf.....	2707
v?Erfc.....	2711
v?CdfNorm.....	2713
v?ErfInv.....	2716
v?ErfcInv.....	2720
v?CdfNormInv.....	2723
Rounding Functions.....	2725

v?Floor.....	2725
v?Ceil.....	2727
v?Trunc.....	2729
v?Round.....	2731
v?NearbyInt.....	2733
v?Rint.....	2735
v?Modf.....	2737
VML Pack/Unpack Functions.....	2739
v?Pack.....	2739
v?Unpack.....	2742
VML Service Functions.....	2744
SetMode.....	2745
GetMode.....	2748
SetErrStatus.....	2749
GetErrStatus.....	2751
ClearErrStatus.....	2751
SetErrorCallBack.....	2752
GetErrorCallBack.....	2756
ClearErrorCallBack.....	2756

Chapter 10: Statistical Functions

Random Number Generators.....	2759
Conventions.....	2760
Mathematical Notation.....	2761
Naming Conventions.....	2762
Basic Generators.....	2767
BRNG Parameter Definition.....	2769
Random Streams.....	2770
Data Types.....	2771
Error Reporting.....	2771
VSL Usage Model.....	2773
Service Routines.....	2775

NewStream.....	2777
NewStreamEx.....	2778
iNewAbstractStream.....	2780
dNewAbstractStream.....	2783
sNewAbstractStream.....	2787
DeleteStream.....	2790
CopyStream.....	2791
CopyStreamState.....	2792
SaveStreamF.....	2794
LoadStreamF.....	2795
LeapfrogStream.....	2797
SkipAheadStream.....	2801
GetStreamStateBrng.....	2805
GetNumRegBrngs.....	2806
Distribution Generators.....	2806
Continuous Distributions.....	2809
Discrete Distributions.....	2858
Advanced Service Routines.....	2881
Data types.....	2881
RegisterBrng.....	2883
GetBrngProperties.....	2885
Formats for User-Designed Generators.....	2886
Convolution and Correlation.....	2890
Overview.....	2890
Naming Conventions.....	2892
Data Types.....	2893
Parameters.....	2894
Task Status and Error Reporting.....	2896
Task Constructors.....	2899
NewTask.....	2900
NewTask1D.....	2903
NewTaskX.....	2906

NewTaskX1D.....	2911
Task Editors.....	2916
SetMode.....	2917
SetInternalPrecision.....	2919
SetStart.....	2921
SetDecimation.....	2923
Task Execution Routines.....	2925
Exec.....	2926
Exec1D.....	2931
ExecX.....	2936
ExecX1D.....	2942
Task Destructors.....	2947
DeleteTask.....	2947
Task Copy.....	2949
CopyTask.....	2949
Usage Examples.....	2951
Mathematical Notation and Definitions.....	2955
Data Allocation.....	2956

Chapter 11: Fourier Transform Functions

FFT Functions.....	2962
Computing FFT.....	2963
FFT Interface.....	2964
Status Checking Functions.....	2965
ErrorClass.....	2966
ErrorMessage.....	2968
Descriptor Manipulation Functions.....	2969
CreateDescriptor.....	2970
CommitDescriptor.....	2972
CopyDescriptor.....	2974
FreeDescriptor.....	2975
FFT Computation Functions.....	2977

ComputeForward.....	2977
ComputeBackward.....	2979
Descriptor Configuration Functions.....	2981
SetValue.....	2981
GetValue.....	2984
Configuration Settings.....	2987
Precision of transform.....	2992
Forward domain of transform.....	2992
Transform dimension and lengths.....	2993
Number of transforms.....	2994
Scale.....	2994
Placement of result.....	2994
Packed formats.....	2994
Storage schemes.....	2999
Number of user threads.....	3011
Input and output distances.....	3012
Strides.....	3013
Ordering.....	3016
Transposition.....	3017
Cluster FFT Functions.....	3017
Computing Cluster FFT.....	3018
Distributing Data among Processes.....	3019
Cluster FFT Interface.....	3022
Descriptor Manipulation Functions.....	3023
CreateDescriptorDM.....	3024
CommitDescriptorDM.....	3026
FreeDescriptorDM.....	3028
FFT Computation Functions.....	3029
ComputeForwardDM.....	3029
ComputeBackwardDM.....	3033
Descriptor Configuration Functions.....	3036
SetValueDM.....	3036

GetValueDM.....	3040
Error Codes.....	3044

Chapter 12: PBLAS Routines

Overview.....	3045
Routine Naming Conventions.....	3046
PBLAS Level 1 Routines.....	3048
p?amax.....	3049
p?asum.....	3050
p?axpy.....	3052
p?copy.....	3053
p?dot.....	3055
p?dotc.....	3056
p?dotu.....	3058
p?nrm2.....	3059
p?scal.....	3061
p?swap.....	3062
PBLAS Level 2 Routines.....	3063
p?gemv.....	3064
p?ger.....	3068
p?gerc.....	3070
p?geru.....	3072
p?hemv.....	3074
p?her.....	3076
p?her2.....	3079
p?symv.....	3081
p?syr.....	3084
p?syr2.....	3086
p?trmv.....	3088
p?trsv.....	3091
PBLAS Level 3 Routines.....	3093
p?gemm.....	3094

p?hemm.....	3097
p?herk.....	3100
p?her2k.....	3102
p?samm.....	3105
p?syrk.....	3108
p?syr2k.....	3111
p?tran.....	3114
p?tranu.....	3115
p?tranc.....	3117
p?trmm.....	3119
p?trsm.....	3122

Chapter 13: Partial Differential Equations Support

Trigonometric Transform Routines.....	3125
Transforms Implemented.....	3126
Sequence of Invoking TT Routines.....	3128
Interface Description.....	3131
TT Routines.....	3132
?_init_trig_transform.....	3132
?_commit_trig_transform.....	3133
?_forward_trig_transform.....	3136
?_backward_trig_transform.....	3138
free_trig_transform.....	3140
Common Parameters.....	3141
Implementation Details.....	3146
Poisson Library Routines	3149
Poisson Library Implemented.....	3150
Sequence of Invoking PL Routines.....	3158
Interface Description.....	3161
PL Routines for the Cartesian Solver.....	3162
?_init_Helmholtz_2D/?_init_Helmholtz_3D.....	3162
?_commit_Helmholtz_2D/?_commit_Helmholtz_3D.....	3165

?_Helmholtz_2D/?_Helmholtz_3D.....	3171
free_Helmholtz_2D/free_Helmholtz_3D.....	3177
PL Routines for the Spherical Solver.....	3178
?_init_sph_p/?_init_sph_np.....	3178
?_commit_sph_p/?_commit_sph_np.....	3180
?_sph_p/?_sph_np.....	3183
free_sph_p/free_sph_np.....	3186
Common Parameters.....	3187
Implementation Details.....	3196
Calling PDE Support Routines from Fortran 90.....	3210

Chapter 14: Nonlinear Optimization Problem Solvers

Organization and Implementation.....	3214
Nonlinear Least Squares Problem without Constraints.....	3215
dtrnlsp_init.....	3216
dtrnlsp_solve.....	3217
dtrnlsp_get.....	3219
dtrnlsp_delete.....	3221
Nonlinear Least Squares Problem with Linear (Bound) Constraints..	3221
dtrnlspbc_init.....	3222
dtrnlspbc_solve.....	3224
dtrnlspbc_get.....	3225
dtrnlspbc_delete.....	3227
Jacobi Matrix Calculation Routines.....	3227
djacobi_init.....	3228
djacobi_solve.....	3229
djacobi_delete.....	3230
djacobi.....	3231
djacobix.....	3232

Chapter 15: Support Functions

Version Information Functions.....	3237
mkl_get_version.....	3238

mkl_get_version_string.....	3240
Threading Control Functions.....	3241
mkl_set_num_threads.....	3242
mkl_domain_set_num_threads.....	3243
mkl_set_dynamic.....	3245
mkl_get_max_threads.....	3246
mkl_domain_get_max_threads.....	3246
mkl_get_dynamic.....	3247
Error Handling Functions.....	3248
xerbla.....	3248
pxerbla.....	3250
Equality Test Functions.....	3251
lsame.....	3251
lsamen.....	3252
Timing Functions.....	3253
second/dsecnd.....	3253
mkl_get_cpu_clocks.....	3254
mkl_get_cpu_frequency.....	3255
mkl_set_cpu_frequency.....	3256
Memory Functions.....	3257
mkl_free_buffers.....	3258
mkl_thread_free_buffers.....	3260
mkl_mem_stat.....	3260
mkl_malloc.....	3261
mkl_free.....	3262
Memory Functions Usage Example.....	3263
Miscellaneous Utility Functions.....	3265
mkl_progress.....	3265
mkl_enable_instructions.....	3268

Chapter 16: BLACS Routines

Matrix Shapes.....	3271
--------------------	------

BLACS Combine Operations.....	3272
?gamx2d.....	3274
?gamn2d.....	3276
?gsum2d.....	3278
BLACS Point To Point Communication.....	3279
?gesd2d.....	3283
?trsd2d.....	3284
?gerv2d.....	3285
?trrv2d.....	3286
BLACS Broadcast Routines.....	3287
?gebs2d.....	3288
?trbs2d.....	3289
?gebr2d.....	3290
?trbr2d.....	3291
BLACS Support Routines.....	3292
Initialization Routines.....	3292
blacs_pinfo.....	3293
blacs_setup.....	3294
blacs_get.....	3295
blacs_set.....	3296
blacs_gridinit.....	3298
blacs_gridmap.....	3299
Destruction Routines.....	3301
blacs_freebuff.....	3301
blacs_gridexit.....	3302
blacs_abort.....	3302
blacs_exit.....	3303
Informational Routines.....	3304
blacs_gridinfo.....	3304
blacs_pnum.....	3305
blacs_pcoord.....	3306
Miscellaneous Routines.....	3306

blacs_barrier.....	3307
BLACS Routines Usage Example.....	3308

Appendix A: Linear Solvers Basics

Sparse Linear Systems.....	3327
Matrix Fundamentals.....	3328
Direct Method.....	3329
Sparse Matrix Storage Formats.....	3334

Appendix B: Routine and Function Arguments

Vector Arguments in BLAS.....	3349
Vector Arguments in VML.....	3350
Matrix Arguments.....	3351

Appendix C: Code Examples

BLAS Code Examples.....	3359
Fourier Transform Functions Code Examples.....	3363
FFT Code Examples.....	3363
Examples of Using Multi-Threading for FFT Computation.....	3372
Examples for Cluster FFT Functions.....	3376
Auxiliary Data Transformations.....	3377

Appendix D: CBLAS Interface to the BLAS

CBLAS Arguments.....	3381
Level 1 CBLAS.....	3382
Level 2 CBLAS.....	3385
Level 3 CBLAS.....	3391
Sparse CBLAS.....	3394

**Appendix E: Specific Features of Fortran 95 Interfaces for
LAPACK Routines**

Interfaces Identical to Netlib.....	3397
-------------------------------------	------

Interfaces with Replaced Argument Names.....	3399
Modified Netlib Interfaces.....	3401
Interfaces Absent From Netlib.....	3402
Interfaces of New Functionality.....	3405

Appendix F: FFTW Interface to Intel® Math Kernel Library

Notational Conventions.....	3407
FFTW2 Interface to Intel(R) Math Kernel Library.....	3407
Wrappers Reference.....	3407
Complex Fast Fourier Transforms.....	3408
Real Fast Fourier Transforms.....	3409
Wisdom Wrappers.....	3409
Memory Allocation.....	3409
Parallel Mode.....	3410
Calling Wrappers from Fortran.....	3410
Installation.....	3411
Creating the Wrapper Library.....	3411
Application Assembling	3412
Running Examples	3412
MPI FFTW	3413
MPI FFTW Wrappers Reference.....	3413
Creating MPI FFTW Wrapper Library.....	3415
Application Assembling with MPI FFTW Wrapper Library	3415
Running Examples	3416
FFTW3 Interface to Intel® Math Kernel Library.....	3417
Using FFTW3 Wrappers.....	3417
Calling Wrappers from Fortran.....	3420
Building Your Own Wrapper Library.....	3421
Building an Application.....	3421
Running Examples	3422

Introducing the Intel® Math Kernel Library

The Intel® Math Kernel Library (Intel® MKL) enables improving performance of scientific, engineering, and financial software that solves large computational problems. Intel MKL provides a set of linear algebra routines, fast Fourier transforms, as well as vectorized math and random number generation functions, all optimized for the latest Intel® processors, including processors with multiple cores (see the *Intel MKL Release Notes* for the full list of supported processors). Intel MKL also performs well on non-Intel processors.

Intel MKL is thread-safe and extensively threaded using the OpenMP* technology.

Getting Help and Support

Getting Help

The online version of the Intel® Math Kernel Library (Intel® MKL) Reference Manual integrates into the Microsoft Visual Studio* development system help on Windows* OS or into the Eclipse* development system help on Linux* OS. For information on how to use the online help, see the online version of the Reference Manual.

Getting Technical Support

Intel MKL provides a product web site that offers timely and comprehensive product information, including product features, white papers, and technical articles. For the latest information, check: <http://www.intel.com/software/products/support>.

Intel also provides a support web site that contains a rich repository of self help information, including getting started tips, known product issues, product errata, license information, user forums, and more (visit <http://www.intel.com/software/products/>).

Registering your product entitles you to one year of technical support and product updates through Intel® Premier Support. Intel Premier Support is an interactive issue management and communication web site providing these services:

- Submit issues and review their status.
- Download product updates anytime of the day.

To register your product, contact Intel, or seek product support, please visit <http://www.intel.com/software/products/support>.

What's New

This Reference Manual documents Intel® Math Kernel Library (Intel® MKL) 10.2 Update 4.

The following function domains have been updated in Intel MKL 10.2 with new functions or enhancements to the existing functionality, reflected in the function descriptions and code examples provided in the manual:

- LAPACK (see [LAPACK Routines: Linear Equations](#), [LAPACK Routines: Least Squares and Eigenvalue Problems](#), [LAPACK Auxiliary and Utility Routines](#)), to reflect LAPACK 3.2 update
- Sparse BLAS (see [BLAS and Sparse BLAS Routines](#)), with new flavors for `?gemm` function
- Sparse Solvers (see [Sparse Solver Routines](#))
- Fast Fourier Transforms (see [Fourier Transform Functions](#))
- Optimization Solvers (see [Optimization Solver Routines](#))
- Support Functions (see [Support Functions](#))

FFTW3 wrappers have been integrated into Intel MKL (see [FFTW3 Interface to Intel® Math Kernel Library](#)).

VML description has been updated with information on special values (see [Vector Mathematical Functions](#)).

For Intel MKL 10.2 Update 2,

- the frontmatter of the manual has been restructured for cross-product consistency and better reading
- Description of [Optimization Solver Routines](#) has been modified and the Appendix on Optimization Solvers Basics has been removed
- several minor bugs have been fixed.

For Intel MKL 10.2 Update 3,

- code examples duplicated from the `examples` folder of the library have been removed from [Appendix C](#)
- the [PARDISO* Solver](#) description has been updated
- description of [Vector Mathematical Functions](#) has been modified
- several minor bugs have been fixed (BLAS, LAPACK, ScaLAPACK, and VML routines).

For Intel MKL 10.2 Update 4,

- the single precision version of the `?cabs1` function has been added (see [BLAS and Sparse BLAS Routines](#)).
- the diagonally dominant tridiagonal routines have been added to the [LAPACK Routines: Linear Equations](#) functions (see `?dttrfb`, `?dttrsrb`, and `?dtsvb`).
- several minor bugs have been fixed (BLAS, ScaLAPACK, FFT, VML, and Support routines).

Notational Conventions

This manual uses the following terms to refer to operating systems:

Windows* OS	This term refers to information that is valid on all supported Windows* operating systems.
Linux* OS	This term refers to information that is valid on all supported Linux* operating systems.
Mac OS* X	This term refers to information that is valid on Intel®-based systems running the Mac OS* X operating system.

This manual uses the following notational conventions:

- Routine name shorthand (for example, `?ungqr` instead of `cungqr/zungqr`).
- Font conventions used for distinction between the text and the code.

Routine Name Shorthand

For shorthand, names that contain a question mark “?” represent groups of routines with similar functionality. Each group typically consists of routines used with four basic data types: single-precision real, double-precision real, single-precision complex, and double-precision complex. The question mark is used to indicate any or all possible varieties of a function; for example:

<code>?swap</code>	Refers to all four data types of the vector-vector <code>?swap</code> routine: <code>sswap</code> , <code>dswap</code> , <code>cswap</code> , and <code>zswap</code> .
--------------------	--

Font Conventions

The following font conventions are used:

UPPERCASE COURIER	Data type used in the description of input and output parameters for Fortran interface. For example, <code>CHARACTER*1</code> .
-------------------	---

lowercase courier	Code examples: <code>a(k+i,j) = matrix(i,j)</code> and data types for C interface, for example, <code>const float*</code>
lowercase courier mixed with UpperCase courier	Function names for C interface, for example, <code>vmlSetMode</code>
<i>lowercase courier</i> <i>italic</i>	Variables in arguments and parameters description. For example, <i>incx</i> .
*	Used as a multiplication symbol in code examples and equations and where required by the Fortran syntax.

Function Domains

The Intel® Math Kernel Library includes Fortran routines and functions optimized for Intel® processor-based computers running operating systems that support multiprocessing. In addition to the Fortran interface, Intel MKL includes a C-language interface for the Discrete Fourier transform functions, as well as for the Vector Mathematical Library and Vector Statistical Library functions. For hardware and software requirements to use Intel MKL, see *Intel® MKL Release Notes*.

The Intel® Math Kernel Library includes the following groups of routines:

- Basic Linear Algebra Subprograms (BLAS):
 - vector operations
 - matrix-vector operations
 - matrix-matrix operations
- Sparse BLAS Level 1, 2, and 3 (basic operations on sparse vectors and matrices)
- LAPACK routines for solving systems of linear equations
- LAPACK routines for solving least squares problems, eigenvalue and singular value problems, and Sylvester's equations
- Auxiliary and utility LAPACK routines
- ScaLAPACK computational, driver and auxiliary routines (only in Intel MKL for Linux* and Windows* operating systems)
- PBLAS routines for distributed vector, matrix-vector, and matrix-matrix operation
- Direct and Iterative Sparse Solver routines

- Vector Mathematical Library (VML) functions for computing core mathematical functions on vector arguments (with Fortran and C interfaces)
- Vector Statistical Library (VSL) functions for generating vectors of pseudorandom numbers with different types of statistical distributions and for performing convolution and correlation computations
- General Fast Fourier Transform (FFT) Functions, providing fast computation of Discrete Fourier Transform via the FFT algorithms and having Fortran and C interfaces
- Cluster FFT functions (only in Intel MKL for Linux* and Windows* operating systems)
- Tools for solving partial differential equations - trigonometric transform routines and Poisson solver
- Optimization Solver routines for solving nonlinear least squares problems through the Trust-Region (TR) algorithms and computing Jacobi matrix by central differences
- Basic Linear Algebra Communication Subprograms (BLACS) that are used to support a linear algebra oriented message passing interface
- GMP arithmetic functions

For specific issues on using the library, also see the *Intel® MKL Release Notes*.

BLAS Routines

The BLAS routines and functions are divided into the following groups according to the operations they perform:

- [BLAS Level 1 Routines](#) perform operations of both addition and reduction on vectors of data. Typical operations include scaling and dot products.
- [BLAS Level 2 Routines](#) perform matrix-vector operations, such as matrix-vector multiplication, rank-1 and rank-2 matrix updates, and solution of triangular systems.
- [BLAS Level 3 Routines](#) perform matrix-matrix operations, such as matrix-matrix multiplication, rank-k update, and solution of triangular systems.

Starting from release 8.0, Intel® MKL also supports Fortran 95 interface to the BLAS routines.

Starting from release 10.1, a number of [BLAS-like Extensions](#) are added to enable the user to perform certain data manipulation, including matrix in-place and out-of-place transposition operations combined with simple matrix arithmetic operations.

Sparse BLAS Routines

The [Sparse BLAS Level 1 Routines and Functions](#) and [Sparse BLAS Level 2 Routines and Level 3 routines and functions](#) operate on sparse vectors and matrices. These routines perform vector operations similar to the BLAS Level 1, 2, and 3 routines. The Sparse BLAS routines take advantage of vector and matrix sparsity: they allow you to store only non-zero elements of vectors and matrices. Intel MKL also supports Fortran 95 interface to Sparse BLAS routines.

LAPACK Routines

The Intel® Math Kernel Library fully supports LAPACK 3.1 set of computational, driver, auxiliary and utility routines.

The original versions of LAPACK from which that part of Intel MKL was derived can be obtained from <http://www.netlib.org/lapack/index.html>. The authors of LAPACK are E. Anderson, Z. Bai, C. Bischof, S. Blackford, J. Demmel, J. Dongarra, J. Du Croz, A. Greenbaum, S. Hammarling, A. McKenney, and D. Sorensen.

The LAPACK routines can be divided into the following groups according to the operations they perform:

- Routines for solving systems of linear equations, factoring and inverting matrices, and estimating condition numbers (see [Chapter 3](#)).
- Routines for solving least squares problems, eigenvalue and singular value problems, and Sylvester's equations (see [Chapter 4](#)).
- Auxiliary and utility routines used to perform certain subtasks, common low-level computation or related tasks (see [Chapter 5](#)).

Starting from release 8.0, Intel MKL also supports Fortran 95 interface to LAPACK computational and driver routines. This interface provides an opportunity for simplified calls of LAPACK routines with fewer required arguments.

ScaLAPACK Routines

The ScaLAPACK package (included only with the Intel® MKL versions for Linux* and Windows* operating systems, see [Chapter 6](#) and [Chapter 7](#)) runs on distributed-memory architectures and includes routines for solving systems of linear equations, solving linear least squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks.

The original versions of ScaLAPACK from which that part of Intel MKL was derived can be obtained from <http://www.netlib.org/scalapack/index.html>. The authors of ScaLAPACK are L. Blackford, J. Choi, A. Cleary, E. D'Azevedo, J. Demmel, I. Dhillon, J. Dongarra, S. Hammarling, G. Henry, A. Petitet, K. Stanley, D. Walker, and R. Whaley.

The Intel MKL version of ScaLAPACK is optimized for Intel® processors and uses MPICH version of MPI as well as Intel MPI.

PBLAS Routines

The PBLAS routines perform operations with distributed vectors and matrices.

- [PBLAS Level 1 Routines](#) perform operations of both addition and reduction on vectors of data. Typical operations include scaling and dot products.
- [PBLAS Level 2 Routines](#) perform distributed matrix-vector operations, such as matrix-vector multiplication, rank-1 and rank-2 matrix updates, and solution of triangular systems.
- [PBLAS Level 3 Routines](#) perform distributed matrix-matrix operations, such as matrix-matrix multiplication, rank-k update, and solution of triangular systems.

Intel MKL provides the PBLAS routines with interface similar to the interface used in the Netlib PBLAS (part of the ScaLAPACK package, see http://www.netlib.org/scalapack/html/pblas_qref.html).

Sparse Solver Routines

Direct sparse solver routines in Intel MKL (see [Chapter 8](#)) solve symmetric and symmetrically-structured sparse matrices with real or complex coefficients. For symmetric matrices, these Intel MKL subroutines can solve both positive-definite and indefinite systems. Intel MKL includes the PARDISO* sparse solver interface as well as an alternative set of user callable direct sparse solver routines.

If you use the sparse solver PARDISO* from Intel MKL, please cite:

O.Schenk and K.Gärtner. Solving unsymmetric sparse systems of linear equations with PARDISO. J. of Future Generation Computer Systems, 20(3):475-487, 2004.

Intel MKL provides also an iterative sparse solver (see [Chapter 8](#)) that uses Sparse BLAS level 2 and 3 routines and works with different sparse data formats.

VML Functions

The Vector Mathematical Library (VML) functions (see [Chapter 9](#)) include a set of highly optimized implementations of certain computationally expensive core mathematical functions (power, trigonometric, exponential, hyperbolic, etc.) that operate on vectors of real and complex numbers.

Application programs that might significantly improve performance with VML include nonlinear programming software, integrals computation, and many others. VML provides interfaces both for Fortran and C languages.

Statistical Functions

The Vector Statistical Library (VSL) contains two sets of functions (see [Chapter 10](#)):

- The first set includes a collection of pseudo- and quasi-random number generator subroutines implementing basic continuous and discrete distributions. To provide best performance, the VSL subroutines use calls to highly optimized Basic Random Number Generators (BRNGs) and a library of vector mathematical functions.
- The second set includes a collection of routines that implement a wide variety of convolution and correlation operations.

Fourier Transform Functions

The Intel® MKL multidimensional Fast Fourier Transform (FFT) functions with mixed radix support (see [Chapter 11](#)) provide uniformity of discrete Fourier transform computation and combine functionality with ease of use. Both Fortran and C interface specification are given. There is also a cluster version of FFT functions, which runs on distributed-memory architectures and is provided only in Intel MKL versions for the Linux* and Windows* operating systems.

The FFT functions provide fast computation via the FFT algorithms for arbitrary lengths. See *the Intel MKL User's Guide* for the specific radices supported.

Partial Differential Equations Support

Intel® MKL provides tools for solving Partial Differential Equations (PDE) (see [Chapter 13](#)). These tools are Trigonometric Transform interface routines and Poisson Library.

The Trigonometric Transform routines may be helpful to users who implement their own solvers similar to the solver that the Poisson Library provides. The users can improve performance of their solvers by using fast sine, cosine, and staggered cosine transforms implemented in the Trigonometric Transform interface.

The Poisson Library is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The Trigonometric Transform interface, which underlies the solver, is based on the Intel MKL FFT interface (refer to [Chapter 11](#)), optimized for Intel® processors.

Optimization Solver Routines

Intel® MKL provides Optimization Solver routines (see [Chapter 14](#)) that can be used to solve nonlinear least squares problems with or without linear (bound) constraints through the Trust-Region (TR) algorithms and compute Jacobi matrix by central differences.

Support Functions

The Intel® MKL support functions (see [Chapter 15](#)) are used to support the operation of the Intel MKL software and provide basic information on the library and library operation, such as the current library version, timing, setting and measuring of CPU frequency, error handling, and memory allocation.

Starting from release 10.0, the Intel MKL support functions provide additional threading control.

Starting from release 10.1, Intel MKL selectively supports a *Progress Routine* feature to track progress of a lengthy computation and/or interrupt the computation using a callback function mechanism. The user application can define a function called `mkl_progress` that is regularly called from the Intel MKL routine supporting the progress routine feature. See [the Progress Routines](#) section in [Chapter 15](#) for reference. Refer to a specific LAPACK or DSS/PARDISO function description to see whether the function supports this feature or not.

BLACS Routines

The Intel® Math Kernel Library implements routines from the BLACS (Basic Linear Algebra Communication Subprograms) package (see [Chapter 16](#)) that are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The original versions of BLACS from which that part of Intel MKL was derived can be obtained from <http://www.netlib.org/blacs/index.html>. The authors of BLACS are Jack Dongarra and R. Clint Whaley.

GMP Arithmetic Functions

Intel® MKL implementation of GMP arithmetic functions includes arbitrary precision arithmetic operations on integer numbers. The interfaces of such functions fully match the GNU Multiple Precision (GMP) Arithmetic Library.

Performance Enhancements

The Intel® Math Kernel Library has been optimized by exploiting both processor and system features and capabilities. Special care has been given to those routines that most profit from cache-management techniques. These especially include matrix-matrix operation routines such as `dgemm()`.

In addition, code optimization techniques have been applied to minimize dependencies of scheduling integer and floating-point units on the results within the processor.

The major optimization techniques used throughout the library include:

- Loop unrolling to minimize loop management costs
- Blocking of data to improve data reuse opportunities
- Copying to reduce chances of data eviction from cache
- Data prefetching to help hide memory latency
- Multiple simultaneous operations (for example, dot products in `dgemm`) to eliminate stalls due to arithmetic unit pipelines
- Use of hardware features such as the SIMD arithmetic units, where appropriate

These are techniques from which the arithmetic code benefits the most.

Parallelism

In addition to the performance enhancements discussed above, Intel® MKL offers performance gains through parallelism provided by the symmetric multiprocessing performance (SMP) feature. You can obtain improvements from SMP in the following ways:

- One way is based on user-managed threads in the program and further distribution of the operations over the threads based on data decomposition, domain decomposition, control decomposition, or some other parallelizing technique. Each thread can use any of the Intel MKL functions (except for the deprecated `?lacom` LAPACK routine) because the library has been designed to be thread-safe.

-
- Another method is to use the FFT and BLAS level 3 routines. They have been parallelized and require no alterations of your application to gain the performance enhancements of multiprocessing. Performance using multiple processors on the level 3 BLAS shows excellent scaling. Since the threads are called and managed within the library, the application does not need to be recompiled thread-safe (see also [Fortran 95 Interface Conventions](#) in Chapter 2).
 - Yet another method is to use *tuned LAPACK routines*. Currently these include the single- and double precision flavors of routines for *QR* factorization of general matrices, triangular factorization of general and symmetric positive-definite matrices, solving systems of equations with such matrices, as well as solving symmetric eigenvalue problems.

For instructions on setting the number of available processors for the BLAS level 3 and LAPACK routines, see *Intel® MKL User's Guide*.

BLAS and Sparse BLAS Routines

2

This chapter describes the Intel® Math Kernel Library implementation of the BLAS and Sparse BLAS routines, and BLAS-like extensions. The routine descriptions are arranged in several sections according to the BLAS level of operation:

- [BLAS Level 1 Routines](#) (vector-vector operations)
- [BLAS Level 2 Routines](#) (matrix-vector operations)
- [BLAS Level 3 Routines](#) (matrix-matrix operations)
- [Sparse BLAS Level 1 Routines](#) (vector-vector operations).
- [Sparse BLAS Level 2 and Level 3 Routines](#) (matrix-vector and matrix-matrix operations)
- [BLAS-like Extensions](#)

Each section presents the routine and function group descriptions in alphabetical order by routine or function group name; for example, the `?asum` group, the `?axpy` group. The question mark in the group name corresponds to different character codes indicating the data type (`s`, `d`, `c`, and `z` or their combination); see [Routine Naming Conventions](#).

When BLAS or Sparse BLAS routines encounter an error, they call the error reporting routine `xerbla`.

In BLAS Level 1 groups `i?amax` and `i?amin`, an “i” is placed before the data-type indicator and corresponds to the index of an element in the vector. These groups are placed in the end of the BLAS Level 1 section.

BLAS Routines

Routine Naming Conventions

BLAS routine names have the following structure:

```
<character> <name> <mod> ( )
```

The `<character>` field indicates the data type:

<code>s</code>	real, single precision
<code>c</code>	complex, single precision
<code>d</code>	real, double precision
<code>z</code>	complex, double precision

Some routines and functions can have combined character codes, such as `sc` or `dz`.

For example, the function `scasum` uses a complex input array and returns a real value.

The `<name>` field, in BLAS level 1, indicates the operation type. For example, the BLAS level 1 routines `?dot`, `?rot`, `?swap` compute a vector dot product, vector rotation, and vector swap, respectively.

In BLAS level 2 and 3, `<name>` reflects the matrix argument type:

<code>ge</code>	general matrix
<code>gb</code>	general band matrix
<code>sy</code>	symmetric matrix
<code>sp</code>	symmetric matrix (packed storage)
<code>sb</code>	symmetric band matrix
<code>he</code>	Hermitian matrix
<code>hp</code>	Hermitian matrix (packed storage)
<code>hb</code>	Hermitian band matrix
<code>tr</code>	triangular matrix
<code>tp</code>	triangular matrix (packed storage)
<code>tb</code>	triangular band matrix.

The `<mod>` field, if present, provides additional details of the operation. BLAS level 1 names can have the following characters in the `<mod>` field:

<code>c</code>	conjugated vector
<code>u</code>	unconjugated vector
<code>g</code>	Givens rotation.

BLAS level 2 names can have the following characters in the `<mod>` field:

<code>mv</code>	matrix-vector product
<code>sv</code>	solving a system of linear equations with matrix-vector operations
<code>r</code>	rank-1 update of a matrix
<code>r2</code>	rank-2 update of a matrix.

BLAS level 3 names can have the following characters in the `<mod>` field:

<code>mm</code>	matrix-matrix product
<code>sm</code>	solving a system of linear equations with matrix-matrix operations
<code>rk</code>	rank- k update of a matrix
<code>r2k</code>	rank- $2k$ update of a matrix.

The examples below illustrate how to interpret BLAS routine names:

<code>ddot</code>	<code><d> <dot></code> : double-precision real vector-vector dot product
<code>cdotc</code>	<code><c> <dot> <c></code> : complex vector-vector dot product, conjugated
<code>scasum</code>	<code><sc> <asum></code> : sum of magnitudes of vector elements, single precision real output and single precision complex input
<code>cdotu</code>	<code><c> <dot> <u></code> : vector-vector dot product, unconjugated, complex
<code>sgemv</code>	<code><s> <ge> <mv></code> : matrix-vector product, general matrix, single precision
<code>ztrmm</code>	<code><z> <tr> <mm></code> : matrix-matrix product, triangular matrix, double-precision complex.

Sparse BLAS level 1 naming conventions are similar to those of BLAS level 1. For more information, see ["Naming Conventions"](#).

Fortran 95 Interface Conventions

Fortran 95 interface to BLAS and Sparse BLAS Level 1 routines is implemented through wrappers that call respective FORTRAN 77 routines. This interface uses such features of Fortran 95 as assumed-shape arrays and optional arguments to provide simplified calls to BLAS and Sparse BLAS Level 1 routines with fewer parameters.

NOTE. For BLAS, Intel MKL offers two types of Fortran 95 interfaces:

- using `mkl_blas.fi` only through `include 'mkl_blas_subroutine.fi'` statement. Such interfaces allow you to make use of the original LAPACK routines with all their arguments
 - using `blas.f90` that includes improved interfaces. This file is used to generate the module files `blas95.mod` and `f95_precision.mod`. The module files `mkl95_blas.mod` and `mkl95_precision.mod` are also generated. See also section "Fortran 95 interfaces and wrappers to LAPACK and BLAS" of *Intel® MKL User's Guide* for details. The module files are used to process the FORTRAN use clauses referencing the BLAS interface: `use blas95` (or an equivalent `use mkl95_blas`) and `use f95_precision` (or an equivalent `use mkl95_precision`).
-

The main conventions used in Fortran 95 interface are as follows:

- The names of parameters used in Fortran 95 interface are typically the same as those used for the respective generic (FORTRAN 77) interface. In rare cases formal argument names may be different. Note that these changes of the formal parameter names have no impact on program semantics and follow the conventions of names unification.

- Some input parameters such as array dimensions are not required in Fortran 95 and are skipped from the calling sequence. Array dimensions are reconstructed from the user data that must exactly follow the required array shape.
- A parameter can be skipped if its value is completely defined by the presence or absence of another parameter in the calling sequence, and the restored value is the only meaningful value for the skipped parameter.
- Parameters specifying the increment values *incx* and *incy* are skipped. In most cases their values are equal to 1. In Fortran 95 an increment with different value can be directly established in the corresponding parameter.
- Some generic parameters are declared as optional in Fortran 95 interface and may or may not be present in the calling sequence. A parameter can be declared optional if it satisfies one of the following conditions:
 1. It can take only a few possible values. The default value of such parameter typically is the first value in the list; all exceptions to this rule are explicitly stated in the routine description.
 2. It has a natural default value.

Optional parameters are given in square brackets in Fortran 95 call syntax.

The particular rules used for reconstructing the values of omitted optional parameters are specific for each routine and are detailed in the respective "Fortran 95 Notes" subsection at the end of routine specification section. If this subsection is omitted, the Fortran 95 interface for the given routine does not differ from the corresponding FORTRAN 77 interface.

Note that this interface is not implemented in the current version of Sparse BLAS Level 2 and Level 3 routines. Fortran 95 interface for each of these routines is given in the "Interfaces - Fortran 95" subsection at the end of the respective routine specification section.

Matrix Storage Schemes

Matrix arguments of BLAS routines can use the following storage schemes:

- *Full storage*: a matrix *A* is stored in a two-dimensional array *a*, with the matrix element a_{ij} stored in the array element $a(i, j)$.
- *Packed storage* scheme allows you to store symmetric, Hermitian, or triangular matrices more compactly: the upper or lower triangle of the matrix is packed by columns in a one-dimensional array.
- *Band storage*: a band matrix is stored compactly in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and *diagonals* of the matrix are stored in rows of the array.

For more information on matrix storage schemes, see “[Matrix Arguments](#)” in Appendix B.

BLAS Level 1 Routines and Functions

BLAS Level 1 includes routines and functions, which perform vector-vector operations. [Table 2-1](#) lists the BLAS Level 1 routine and function groups and the data types associated with them.

Table 2-1 BLAS Level 1 Routine and Function Groups and Their Data Types

Routine or Function Group	Data Types	Description
<code>?asum</code>	s, d, sc, dz	Sum of vector magnitudes (functions)
<code>?axpy</code>	s, d, c, z	Scalar-vector product (routines)
<code>?copy</code>	s, d, c, z	Copy vector (routines)
<code>?dot</code>	s, d	Dot product (functions)
<code>?sdot</code>	sd, d	Dot product with extended precision (functions)
<code>?dotc</code>	c, z	Dot product conjugated (functions)
<code>?dotu</code>	c, z	Dot product unconjugated (functions)
<code>?nrm2</code>	s, d, sc, dz	Vector 2-norm (Euclidean norm) (functions)
<code>?rot</code>	s, d, cs, zd	Plane rotation of points (routines)
<code>?rotg</code>	s, d, c, z	Givens rotation of points (routines)
<code>?rotm</code>	s, d	Modified plane rotation of points (routines)
<code>?rotmg</code>	s, d	Givens modified plane rotation of points (routines)
<code>?scal</code>	s, d, c, z, cs, zd	Vector-scalar product (routines)
<code>?swap</code>	s, d, c, z	Vector-vector swap (routines)
<code>i?amax</code>	s, d, c, z	Index of the maximum absolute value element of a vector (functions)

Routine or Function Group	Data Types	Description
<code>i?amin</code>	<code>s, d, c, z</code>	Index of the minimum absolute value element of a vector (functions)
<code>?cabs1</code>	<code>s, d</code>	Auxiliary functions, compute the absolute value of a complex number of single or double precision

?asum

Computes the sum of magnitudes of the vector elements.

Syntax

FORTRAN 77:

```
res = sasum(n, x, incx)
res = scasum(n, x, incx)
res = dasum(n, x, incx)
res = dzasum(n, x, incx)
```

Fortran 95:

```
res = asum(x)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?asum` routine computes the sum of the magnitudes of elements of a real vector, or the sum of magnitudes of the real and imaginary parts of elements of a complex vector:

$$res = |\operatorname{Re} x(1)| + |\operatorname{Im} x(1)| + |\operatorname{Re} x(2)| + |\operatorname{Im} x(2)| + \dots + |\operatorname{Re} x(n)| + |\operatorname{Im} x(n)|,$$

where x is a vector with a number of elements that equals n .

Input Parameters

n	INTEGER. Specifies the number of elements in vector x .
x	REAL for <code>sasum</code>

DOUBLE PRECISION for `dasum`
 COMPLEX for `scasum`
 DOUBLE COMPLEX for `dzasum`

`incx` Array, DIMENSION at least $(1 + (n-1)*abs(incx))$.
 INTEGER. Specifies the increment for indexing vector `x`.

Output Parameters

`res` REAL for `sasum`
 DOUBLE PRECISION for `dasum`
 REAL for `scasum`
 DOUBLE PRECISION for `dzasum`
 Contains the sum of magnitudes of real and imaginary parts
 of all elements of the vector.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `asum` interface are the following:

`x` Holds the array of size `n`.

?axpy

Computes a vector-scalar product and adds the result to a vector.

Syntax

FORTRAN 77:

```
call saxpy(n, a, x, incx, y, incy)
call daxpy(n, a, x, incx, y, incy)
call caxpy(n, a, x, incx, y, incy)
call zaxpy(n, a, x, incx, y, incy)
```

Fortran 95:

```
call axpy(x, y [,a])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?axpy` routines perform a vector-vector operation defined as

$$y := a*x + y$$

where:

a is a scalar

x and y are vectors each with a number of elements that equals n .

Input Parameters

n	INTEGER. Specifies the number of elements in vectors x and y .
a	REAL for saxpy DOUBLE PRECISION for daxpy COMPLEX for caxpy DOUBLE COMPLEX for zaxpy Specifies the scalar a .
x	REAL for saxpy DOUBLE PRECISION for daxpy COMPLEX for caxpy DOUBLE COMPLEX for zaxpy Array, DIMENSION at least $(1 + (n-1)*abs(incx))$.
$incx$	INTEGER. Specifies the increment for the elements of x .
y	REAL for saxpy DOUBLE PRECISION for daxpy COMPLEX for caxpy DOUBLE COMPLEX for zaxpy Array, DIMENSION at least $(1 + (n-1)*abs(incy))$.
$incy$	INTEGER. Specifies the increment for the elements of y .

Output Parameters

y Contains the updated vector y .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `axpy` interface are the following:

x	Holds the array of size n .
y	Holds the array of size n .
a	The default value is 1.

?copy

Copies vector to another vector.

Syntax

FORTRAN 77:

```
call scopy( $n$ ,  $x$ ,  $incx$ ,  $y$ ,  $incy$ )
call dcopy( $n$ ,  $x$ ,  $incx$ ,  $y$ ,  $incy$ )
call ccopy( $n$ ,  $x$ ,  $incx$ ,  $y$ ,  $incy$ )
call zcopy( $n$ ,  $x$ ,  $incx$ ,  $y$ ,  $incy$ )
```

Fortran 95:

```
call copy( $x$ ,  $y$ )
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?copy` routines perform a vector-vector operation defined as

$$y = x,$$

where x and y are vectors.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in vectors <i>x</i> and <i>y</i> .
<i>x</i>	REAL for <i>scopy</i> DOUBLE PRECISION for <i>dcopy</i> COMPLEX for <i>ccopy</i> DOUBLE COMPLEX for <i>zcopy</i> Array, DIMENSION at least $(1 + (n-1)*abs(incx))$.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .
<i>y</i>	REAL for <i>scopy</i> DOUBLE PRECISION for <i>dcopy</i> COMPLEX for <i>ccopy</i> DOUBLE COMPLEX for <i>zcopy</i> Array, DIMENSION at least $(1 + (n-1)*abs(incy))$.
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> .

Output Parameters

<i>y</i>	Contains a copy of the vector <i>x</i> if <i>n</i> is positive. Otherwise, parameters are unaltered.
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *copy* interface are the following:

<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .

?dot

Computes a vector-vector dot product.

Syntax

FORTRAN 77:

```
res = sdot(n, x, incx, y, incy)
```

```
res = ddot(n, x, incx, y, incy)
```

Fortran 95:

```
res = dot(x, y)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?dot routines perform a vector-vector reduction operation defined as

$$\text{res} = \sum(x*y),$$

where x and y are vectors.

Input Parameters

n	INTEGER. Specifies the number of elements in vectors x and y .
x	REAL for sdot DOUBLE PRECISION for ddot Array, DIMENSION at least $(1+(n-1)*\text{abs}(incx))$.
$incx$	INTEGER. Specifies the increment for the elements of x .
y	REAL for sdot DOUBLE PRECISION for ddot Array, DIMENSION at least $(1+(n-1)*\text{abs}(incy))$.
$incy$	INTEGER. Specifies the increment for the elements of y .

Output Parameters

res	REAL for sdot
-------	---------------

DOUBLE PRECISION for `ddot`
Contains the result of the dot product of x and y , if n is positive. Otherwise, res contains 0.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dot` interface are the following:

x	Holds the vector with the number of elements n .
y	Holds the vector with the number of elements n .

?sdot

Computes a vector-vector dot product with extended precision.

Syntax

FORTRAN 77:

```
res = sdsdot(n, sb, sx, incx, sy, incy)
res = dsdot(n, sx, incx, sy, incy)
```

Fortran 95:

```
res = sdot(sx, sy)
res = sdot(sx, sy, sb)
```

Description

This routine is declared in `mk1_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mk1_blas.h` for C interface.

The `?sdot` routines compute the inner product of two vectors with extended precision. Both routines use extended precision accumulation of the intermediate results, but the `sdsdot` routine outputs the final result in single precision, whereas the `dsdot` routine outputs the double precision result. The function `sdsdot` also adds scalar value sb to the inner product.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in the input vectors <i>sx</i> and <i>sy</i> .
<i>sb</i>	REAL. Single precision scalar to be added to inner product (for the function <code>sdsdot</code> only).
<i>sx, sy</i>	REAL. Arrays, DIMENSION at least $(1+(n-1)*abs(incx))$ and $(1+(n-1)*abs(incy))$, respectively. Contain the input single precision vectors.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>sx</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>sy</i> .

Output Parameters

<i>res</i>	REAL for <code>sdsdot</code> DOUBLE PRECISION for <code>dsdot</code> Contains the result of the dot product of <i>sx</i> and <i>sy</i> (with <i>sb</i> added for <code>sdsdot</code>), if <i>n</i> is positive. Otherwise, <i>res</i> contains <i>sb</i> for <code>sdsdot</code> and 0 for <code>dsdot</code> .
------------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sdot` interface are the following:

<i>sx</i>	Holds the vector with the number of elements <i>n</i> .
<i>sy</i>	Holds the vector with the number of elements <i>n</i> .

NOTE. Note that scalar parameter *sb* is declared as a required parameter in Fortran 95 interface for the function `sdot` to distinguish between function flavors that output final result in different precision.

?dotc

Computes a dot product of a conjugated vector with another vector.

Syntax

FORTRAN 77:

```
res = cdotc(n, x, incx, y, incy)
```

```
res = zdotc(n, x, incx, y, incy)
```

Fortran 95:

```
res = dotc(x, y)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?dotc` routines perform a vector-vector operation defined as

$$res = \sum(\text{conjg}(x)*y)$$

where x and y are n -element vectors.

Input Parameters

n	INTEGER. Specifies the number of elements in vectors x and y .
x	COMPLEX for <code>cdotc</code> DOUBLE COMPLEX for <code>zdotc</code> Array, DIMENSION at least $(1 + (n - 1)*\text{abs}(incx))$.
$incx$	INTEGER. Specifies the increment for the elements of x .
y	COMPLEX for <code>cdotc</code> DOUBLE COMPLEX for <code>zdotc</code> Array, DIMENSION at least $(1 + (n - 1)*\text{abs}(incy))$.
$incy$	INTEGER. Specifies the increment for the elements of y .

Output Parameters

res	COMPLEX for <code>cdotc</code>
-------	--------------------------------

DOUBLE COMPLEX for `zdotc`
 Contains the result of the dot product of the conjugated x and unconjugated y , if n is positive. Otherwise, res contains 0.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dotc` interface are the following:

x	Holds the vector with the number of elements n .
y	Holds the vector with the number of elements n .

?dotu

Computes a vector-vector dot product.

Syntax

FORTRAN 77:

```
res = cdotu(n, x, incx, y, incy)
```

```
res = zdotu(n, x, incx, y, incy)
```

Fortran 95:

```
res = dotu(x, y)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?dotu` routines perform a vector-vector reduction operation defined as

$$res = \sum(x*y)$$

where x and y are n -element complex vectors.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in vectors <i>x</i> and <i>y</i> .
<i>x</i>	COMPLEX for <code>cdotu</code> DOUBLE COMPLEX for <code>zdotu</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .
<i>y</i>	COMPLEX for <code>cdotu</code> DOUBLE COMPLEX for <code>zdotu</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$.
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> .

Output Parameters

<i>res</i>	COMPLEX for <code>cdotu</code> DOUBLE COMPLEX for <code>zdotu</code> Contains the result of the dot product of <i>x</i> and <i>y</i> , if <i>n</i> is positive. Otherwise, <i>res</i> contains 0.
------------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dotu` interface are the following:

<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .

?nrm2

Computes the Euclidean norm of a vector.

Syntax

FORTRAN 77:

```
res = snrm2(n, x, incx)
```

```
res = dnrm2(n, x, incx)
```

```
res = scnrm2(n, x, incx)
res = dznrm2(n, x, incx)
```

Fortran 95:

```
res = nrm2(x)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?nrm2` routines perform a vector reduction operation defined as

$$res = \|x\|,$$

where:

x is a vector,

res is a value containing the Euclidean norm of the elements of x .

Input Parameters

n	INTEGER. Specifies the number of elements in vector x .
x	REAL for <code>snrm2</code> DOUBLE PRECISION for <code>dnrm2</code> COMPLEX for <code>scnrm2</code> DOUBLE COMPLEX for <code>dznrm2</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incx))$.
$incx$	INTEGER. Specifies the increment for the elements of x .

Output Parameters

res	REAL for <code>snrm2</code> DOUBLE PRECISION for <code>dnrm2</code> REAL for <code>scnrm2</code> DOUBLE PRECISION for <code>dznrm2</code> Contains the Euclidean norm of the vector x .
-------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `nrm2` interface are the following:

`x` Holds the vector with the number of elements `n`.

?rot

Performs rotation of points in the plane.

Syntax

FORTRAN 77:

```
call srot(n, x, incx, y, incy, c, s)
call drot(n, x, incx, y, incy, c, s)
call csrot(n, x, incx, y, incy, c, s)
call zdrot(n, x, incx, y, incy, c, s)
```

Fortran 95:

```
call rot(x, y, c, s)
```

Description

This routine is declared in `mk1_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mk1_blas.h` for C interface.

Given two complex vectors `x` and `y`, each vector element of these vectors is replaced as follows:

$$x(i) = c*x(i) + s*y(i)$$

$$y(i) = c*y(i) - s*x(i)$$

Input Parameters

<code>n</code>	INTEGER. Specifies the number of elements in vectors <code>x</code> and <code>y</code> .
<code>x</code>	REAL for <code>srot</code> DOUBLE PRECISION for <code>drot</code> COMPLEX for <code>csrot</code> DOUBLE COMPLEX for <code>zdrot</code> Array, DIMENSION at least $(1 + (n-1)*abs(incx))$.
<code>incx</code>	INTEGER. Specifies the increment for the elements of <code>x</code> .
<code>y</code>	REAL for <code>srot</code>

	DOUBLE PRECISION for drot
	COMPLEX for csrot
	DOUBLE COMPLEX for zdrot
	Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incy))$.
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> .
<i>c</i>	REAL for srot DOUBLE PRECISION for drot REAL for csrot DOUBLE PRECISION for zdrot A scalar.
<i>s</i>	REAL for srot DOUBLE PRECISION for drot REAL for csrot DOUBLE PRECISION for zdrot A scalar.

Output Parameters

<i>x</i>	Each element is replaced by $c*x + s*y$.
<i>y</i>	Each element is replaced by $c*y - s*x$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `rot` interface are the following:

<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .

?rotg

Computes the parameters for a Givens rotation.

Syntax

FORTRAN 77:

```
call srotg(a, b, c, s)
```

```
call drotg(a, b, c, s)
call crotg(a, b, c, s)
call zrotg(a, b, c, s)
```

Fortran 95:

```
call rotg(a, b, c, s)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

Given the Cartesian coordinates (a, b) of a point p , these routines return the parameters a , b , c , and s associated with the Givens rotation that zeros the y -coordinate of the point.

See a more accurate LAPACK version [?lartg](#).

Input Parameters

a	REAL for srotg DOUBLE PRECISION for drotg COMPLEX for crotg DOUBLE COMPLEX for zrotg Provides the x -coordinate of the point p .
b	REAL for srotg DOUBLE PRECISION for drotg COMPLEX for crotg DOUBLE COMPLEX for zrotg Provides the y -coordinate of the point p .

Output Parameters

a	Contains the parameter r associated with the Givens rotation.
b	Contains the parameter z associated with the Givens rotation.
c	REAL for srotg DOUBLE PRECISION for drotg REAL for crotg DOUBLE PRECISION for zrotg

	Contains the parameter c associated with the Givens rotation.
s	REAL for srotg DOUBLE PRECISION for drotg COMPLEX for crotg DOUBLE COMPLEX for zrotg Contains the parameter s associated with the Givens rotation.

?rotm

Performs rotation of points in the modified plane.

Syntax

FORTRAN 77:

```
call srotm(n, x, incx, y, incy, param)
call drotm(n, x, incx, y, incy, param)
```

Fortran 95:

```
call rotm(x, y, param)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

Given two complex vectors x and y , each vector element of these vectors is replaced as follows:

$$x(i) = H*x(i) + H*y(i)$$

$$y(i) = H*y(i) - H*x(i)$$

where H is a modified Givens transformation matrix whose values are stored in the `param(2)` through `param(5)` array. See discussion on the `param` argument.

Input Parameters

n	INTEGER. Specifies the number of elements in vectors x and y .
x	REAL for srotm DOUBLE PRECISION for drotm

incx Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incx))$.
 INTEGER. Specifies the increment for the elements of *x*.
y REAL for srotm
 DOUBLE PRECISION for drotm
 Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incy))$.
incy INTEGER. Specifies the increment for the elements of *y*.
param REAL for srotm
 DOUBLE PRECISION for drotm
 Array, DIMENSION 5.
 The elements of the *param* array are:
param(1) contains a switch, *flag*. *param(2-5)* contain *h11*,
h21, *h12*, and *h22*, respectively, the components of the array
H.
 Depending on the values of *flag*, the components of *H* are
 set as follows:

$$flag = -1. : H = \begin{bmatrix} h11 & h12 \\ h21 & h22 \end{bmatrix}$$

$$flag = 0. : H = \begin{bmatrix} 1. & h12 \\ h21 & 1. \end{bmatrix}$$

$$flag = 1. : H = \begin{bmatrix} h11 & 1. \\ -1 & h22 \end{bmatrix}$$

$$flag = -2. : H = \begin{bmatrix} 1. & 0. \\ 0. & 1. \end{bmatrix}$$

In the last three cases, the matrix entries of 1., -1., and 0.
 are assumed based on the value of *flag* and are not
 required to be set in the *param* vector.

Output Parameters

x	Each element is replaced by $h_{11}x + h_{12}y$.
y	Each element is replaced by $h_{21}x + h_{22}y$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `rotm` interface are the following:

x	Holds the vector with the number of elements n .
y	Holds the vector with the number of elements n .

?rotmg

Computes the parameters for a modified Givens rotation.

Syntax

FORTRAN 77:

```
call srotmg(d1, d2, x1, y1, param)
call drotmg(d1, d2, x1, y1, param)
```

Fortran 95:

```
call rotmg(d1, d2, x1, y1, param)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

Given Cartesian coordinates (x_1, y_1) of an input vector, these routines compute the components of a modified Givens transformation matrix H that zeros the y -component of the resulting vector:

$$\begin{bmatrix} x \\ 0 \end{bmatrix} = H \begin{bmatrix} \sqrt{d_1}x_1 \\ \sqrt{d_2}y_1 \end{bmatrix}$$

Input Parameters

<i>d1</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the scaling factor for the <i>x</i> -coordinate of the input vector.
<i>d2</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the scaling factor for the <i>y</i> -coordinate of the input vector.
<i>x1</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the <i>x</i> -coordinate of the input vector.
<i>y1</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the <i>y</i> -coordinate of the input vector.

Output Parameters

<i>d1</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the first diagonal element of the updated matrix.
<i>d2</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the second diagonal element of the updated matrix.
<i>x1</i>	REAL for srotmg DOUBLE PRECISION for drotmg Provides the <i>x</i> -coordinate of the rotated vector before scaling.
<i>param</i>	REAL for srotmg DOUBLE PRECISION for drotmg Array, DIMENSION 5. The elements of the <i>param</i> array are: <i>param(1)</i> contains a switch, <i>flag</i> . <i>param(2-5)</i> contain <i>h11</i> , <i>h21</i> , <i>h12</i> , and <i>h22</i> , respectively, the components of the array <i>H</i> .

Depending on the values of *flag*, the components of *H* are set as follows:

$$flag = -1. : H = \begin{bmatrix} h11 & h12 \\ h21 & h22 \end{bmatrix}$$

$$flag = 0. : H = \begin{bmatrix} 1. & h12 \\ h21 & 1. \end{bmatrix}$$

$$flag = 1. : H = \begin{bmatrix} h11 & 1. \\ -1 & h22 \end{bmatrix}$$

$$flag = -2. : H = \begin{bmatrix} 1. & 0. \\ 0. & 1. \end{bmatrix}$$

In the last three cases, the matrix entries of 1., -1., and 0. are assumed based on the value of *flag* and are not required to be set in the *param* vector.

?scal

Computes the product of a vector by a scalar.

Syntax

FORTRAN 77:

```
call sscal(n, a, x, incx)
call dscal(n, a, x, incx)
call cscal(n, a, x, incx)
call zscal(n, a, x, incx)
call csscal(n, a, x, incx)
```

```
call zdscal(n, a, x, incx)
```

Fortran 95:

```
call scal(x, a)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?scal` routines perform a vector operation defined as

$$x = a*x$$

where:

a is a scalar, x is an n -element vector.

Input Parameters

n	INTEGER. Specifies the number of elements in vector x .
a	REAL for <code>sscal</code> and <code>csscal</code> DOUBLE PRECISION for <code>dscal</code> and <code>zdscal</code> COMPLEX for <code>cscal</code> DOUBLE COMPLEX for <code>zscal</code> Specifies the scalar a .
x	REAL for <code>sscal</code> DOUBLE PRECISION for <code>dscal</code> COMPLEX for <code>cscal</code> and <code>csscal</code> DOUBLE COMPLEX for <code>zscal</code> and <code>zdscal</code> Array, DIMENSION at least $(1 + (n - 1)*abs(incx))$.
$incx$	INTEGER. Specifies the increment for the elements of x .

Output Parameters

x	Updated vector x .
-----	----------------------

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `scal` interface are the following:

x Holds the vector with the number of elements *n*.

?swap

Swaps a vector with another vector.

Syntax

FORTRAN 77:

```
call sswap(n, x, incx, y, incy)
call dswap(n, x, incx, y, incy)
call cswap(n, x, incx, y, incy)
call zswap(n, x, incx, y, incy)
```

Fortran 95:

```
call swap(x, y)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

Given two vectors *x* and *y*, the ?swap routines return vectors *y* and *x* swapped, each replacing the other.

Input Parameters

<i>n</i>	INTEGER. Specifies the number of elements in vectors <i>x</i> and <i>y</i> .
<i>x</i>	REAL for sswap DOUBLE PRECISION for dswap COMPLEX for cswap DOUBLE COMPLEX for zswap Array, DIMENSION at least $(1 + (n-1)*abs(incx))$.
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> .
<i>y</i>	REAL for sswap DOUBLE PRECISION for dswap COMPLEX for cswap

`DOUBLE COMPLEX` for `zswap`
Array, DIMENSION at least $(1 + (n-1)*abs(incy))$.
`incy` INTEGER. Specifies the increment for the elements of `y`.

Output Parameters

`x` Contains the resultant vector `x`, that is, the input vector `y`.
`y` Contains the resultant vector `y`, that is, the input vector `x`.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `swap` interface are the following:

`x` Holds the vector with the number of elements `n`.
`y` Holds the vector with the number of elements `n`.

i?amax

Finds the index of the element with maximum absolute value.

Syntax

FORTRAN 77:

`index = isamax(n, x, incx)`

`index = idamax(n, x, incx)`

`index = icamax(n, x, incx)`

`index = izamax(n, x, incx)`

Fortran 95:

`index = iamax(x)`

Description

This function is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

Given a vector x , the $i?amax$ functions return the position of the vector element $x(i)$ that has the largest absolute value for real flavors, or the largest sum $|\operatorname{Re}(x(i))| + |\operatorname{Im}(x(i))|$ for complex flavors.

If n is not positive, 0 is returned.

If more than one vector element is found with the same largest absolute value, the index of the first one encountered is returned.

Input Parameters

n	INTEGER. Specifies the number of elements in vector x .
x	REAL for $isamax$ DOUBLE PRECISION for $idamax$ COMPLEX for $icamax$ DOUBLE COMPLEX for $izamax$ Array, DIMENSION at least $(1+(n-1)*abs(incx))$.
$incx$	INTEGER. Specifies the increment for the elements of x .

Output Parameters

$index$	INTEGER. Contains the position of vector element x that has the largest absolute value.
---------	---

Fortran 95 Interface Notes

Functions and routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the function $iamax$ interface are the following:

x	Holds the vector with the number of elements n .
-----	--

$i?amin$

Finds the index of the element with the smallest absolute value.

Syntax

FORTRAN 77:

```
 $index = isamin(n, x, incx)$ 
```

```
index = idamin(n, x, incx)
```

```
index = icamin(n, x, incx)
```

```
index = izamin(n, x, incx)
```

Fortran 95:

```
index = iamin(x)
```

Description

This function is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

Given a vector x , the `i?amin` functions return the position of the vector element $x(i)$ that has the smallest absolute value for real flavors, or the smallest sum $|\operatorname{Re}(x(i))| + |\operatorname{Im}(x(i))|$ for complex flavors.

If n is not positive, 0 is returned.

If more than one vector element is found with the same smallest absolute value, the index of the first one encountered is returned.

Input Parameters

<i>n</i>	INTEGER. On entry, n specifies the number of elements in vector x .
<i>x</i>	REAL for <code>isamin</code> DOUBLE PRECISION for <code>idamin</code> COMPLEX for <code>icamin</code> DOUBLE COMPLEX for <code>izamin</code> Array, DIMENSION at least $(1+(n-1)*\operatorname{abs}(\operatorname{incx}))$.
<i>incx</i>	INTEGER. Specifies the increment for the elements of x .

Output Parameters

<i>index</i>	INTEGER. Contains the position of vector element x that has the smallest absolute value.
--------------	--

Fortran 95 Interface Notes

Functions and routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the function `iamin` interface are the following:

`x` Holds the vector with the number of elements `n`.

?cabs1

Computes absolute value of complex number.

Syntax

FORTRAN 77:

```
res = scabs1(z)
```

```
res = dcabs1(z)
```

Fortran 95:

```
res = cabs1(z)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?cabs1` is an auxiliary routine for a few BLAS Level 1 routines. This routine performs an operation defined as

$$res = |\operatorname{Re}(z)| + |\operatorname{Im}(z)|$$

where z is a scalar, and res is a value containing the absolute value of a complex number z .

Input Parameters

`z` COMPLEX scalar for `scabs1`.
DOUBLE COMPLEX scalar for `dcabs1`.

Output Parameters

`res` REAL for `scabs1`.
DOUBLE PRECISION for `dcabs1`.
Contains the absolute value of a complex number z .

BLAS Level 2 Routines

This section describes BLAS Level 2 routines, which perform matrix-vector operations. [Table 2-2](#) lists the BLAS Level 2 routine groups and the data types associated with them.

Table 2-2 BLAS Level 2 Routine Groups and Their Data Types

Routine Groups	Data Types	Description
?gbmv	s, d, c, z	Matrix-vector product using a general band matrix
?gemv	s, d, c, z	Matrix-vector product using a general matrix
?ger	s, d	Rank-1 update of a general matrix
?gerc	c, z	Rank-1 update of a conjugated general matrix
?geru	c, z	Rank-1 update of a general matrix, unconjugated
?hbmV	c, z	Matrix-vector product using a Hermitian band matrix
?hemv	c, z	Matrix-vector product using a Hermitian matrix
?her	c, z	Rank-1 update of a Hermitian matrix
?her2	c, z	Rank-2 update of a Hermitian matrix
?hpmv	c, z	Matrix-vector product using a Hermitian packed matrix
?hpr	c, z	Rank-1 update of a Hermitian packed matrix
?hpr2	c, z	Rank-2 update of a Hermitian packed matrix
?sbmv	s, d	Matrix-vector product using symmetric band matrix
?spmv	s, d	Matrix-vector product using a symmetric packed matrix
?spr	s, d	Rank-1 update of a symmetric packed matrix
?spr2	s, d	Rank-2 update of a symmetric packed matrix

Routine Groups	Data Types	Description
?symv	s, d	Matrix-vector product using a symmetric matrix
?syr	s, d	Rank-1 update of a symmetric matrix
?syr2	s, d	Rank-2 update of a symmetric matrix
?tbmv	s, d, c, z	Matrix-vector product using a triangular band matrix
?tbsv	s, d, c, z	Solution of a linear system of equations with a triangular band matrix
?tpmv	s, d, c, z	Matrix-vector product using a triangular packed matrix
?tpsv	s, d, c, z	Solution of a linear system of equations with a triangular packed matrix
?trmv	s, d, c, z	Matrix-vector product using a triangular matrix
?trsv	s, d, c, z	Solution of a linear system of equations with a triangular matrix

?gbmv

Computes a matrix-vector product using a general band matrix

Syntax

FORTRAN 77:

```
call sgbmv(trans, m, n, kl, ku, alpha, a, lda, x, incx, beta, y, incy)
call dgbmv(trans, m, n, kl, ku, alpha, a, lda, x, incx, beta, y, incy)
call cgbmv(trans, m, n, kl, ku, alpha, a, lda, x, incx, beta, y, incy)
call zgbmv(trans, m, n, kl, ku, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call gbmv(a, x, y [,kl] [,m] [,alpha] [,beta] [,trans])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?gbmv` routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y$$

or

$$y := \alpha * A' * x + \beta * y,$$

or

$$y := \alpha * \text{conjg}(A') * x + \beta * y,$$

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*n* band matrix, with *kl* sub-diagonals and *ku* super-diagonals.

Input Parameters

<i>trans</i>	CHARACTER*1. Specifies the operation: If <i>trans</i> = 'N' or 'n', then $y := \alpha * A * x + \beta * y$ If <i>trans</i> = 'T' or 't', then $y := \alpha * A' * x + \beta * y$ If <i>trans</i> = 'C' or 'c', then $y := \alpha * \text{conjg}(A') * x + \beta * y$
<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>kl</i>	INTEGER. Specifies the number of sub-diagonals of the matrix <i>A</i> . The value of <i>kl</i> must satisfy $0 \leq kl$.
<i>ku</i>	INTEGER. Specifies the number of super-diagonals of the matrix <i>A</i> . The value of <i>ku</i> must satisfy $0 \leq ku$.
<i>alpha</i>	REAL for <code>sgbmv</code> DOUBLE PRECISION for <code>dgbmv</code>

COMPLEX for cgbmv
 DOUBLE COMPLEX for zgbmv
 Specifies the scalar *alpha*.

a REAL for sgbmv
 DOUBLE PRECISION for dgbmv
 COMPLEX for cgbmv
 DOUBLE COMPLEX for zgbmv
 Array, DIMENSION (*lda*, *n*).
 Before entry, the leading (*kl* + *ku* + 1) by *n* part of the array *a* must contain the matrix of coefficients. This matrix must be supplied column-by-column, with the leading diagonal of the matrix in row (*ku* + 1) of the array, the first super-diagonal starting at position 2 in row *ku*, the first sub-diagonal starting at position 1 in row (*ku* + 2), and so on. Elements in the array *a* that do not correspond to elements in the band matrix (such as the top left *ku* by *ku* triangle) are not referenced.
 The following program segment transfers a band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
  k = ku + 1 - j
  do 10, i = max(1, j-ku), min(m, j+kl)
    a(k+i, j) = matrix(i,j)
  10 continue
20 continue
  
```

lda INTEGER. Specifies the first dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least (*kl* + *ku* + 1).

x REAL for sgbmv
 DOUBLE PRECISION for dgbmv
 COMPLEX for cgbmv
 DOUBLE COMPLEX for zgbmv

	Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incx))$ when <i>trans</i> = 'N' or 'n', and at least $(1 + (m - 1) * \text{abs}(incx))$ otherwise. Before entry, the array <i>x</i> must contain the vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . <i>incx</i> must not be zero.
<i>beta</i>	REAL for sgbmv DOUBLE PRECISION for dgbmv COMPLEX for cgbmv DOUBLE COMPLEX for zgbmv Specifies the scalar beta. When <i>beta</i> is equal to zero, then <i>y</i> need not be set on input.
<i>y</i>	REAL for sgbmv DOUBLE PRECISION for dgbmv COMPLEX for cgbmv DOUBLE COMPLEX for zgbmv Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(incy))$ when <i>trans</i> = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(incy))$ otherwise. Before entry, the incremented array <i>y</i> must contain the vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Updated vector <i>y</i> .
----------	---------------------------

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gbmv* interface are the following:

<i>a</i>	Holds the array <i>a</i> of size $(kl+ku+1, n)$. Contains a banded matrix $m * n$ with <i>kl</i> lower diagonal and <i>ku</i> upper diagonal.
<i>x</i>	Holds the vector with the number of elements <i>rx</i> , where <i>rx</i> = <i>n</i> if <i>trans</i> = 'N', <i>rx</i> = <i>m</i> otherwise.

<i>y</i>	Holds the vector with the number of elements r_y , where $r_y = m$ if $trans = 'N'$, $r_y = n$ otherwise.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>kl</i>	If omitted, assumed $kl = ku$, that is, the number of lower diagonals equals the number of the upper diagonals.
<i>ku</i>	Restored as $ku = lda - kl - 1$, where lda is the first dimension of matrix <i>A</i> .
<i>m</i>	If omitted, assumed $m = n$, that is, a square matrix.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?gemv

Computes a matrix-vector product using a general matrix

Syntax

FORTRAN 77:

```
call sgemv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call dgemv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call cgemv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
call zgemv(trans, m, n, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call gemv(a, x, y [,alpha][,beta] [,trans])
```

Description

This routine is declared in `mk1_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mk1_blas.h` for C interface.

The ?gemv routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

or

$$y := \alpha * A' * x + \beta * y,$$

or

$$y := \alpha * \text{conjg}(A') * x + \beta * y,$$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- n matrix.

Input Parameters

<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $y := \alpha * A * x + \beta * y$; if <i>trans</i> = 'T' or 't', then $y := \alpha * A' * x + \beta * y$; if <i>trans</i> = 'C' or 'c', then $y := \alpha * \text{conjg}(A') * x + \beta * y$.
<i>m</i>	INTEGER. Specifies the number of rows of the matrix A . The value of m must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix A . The value of n must be at least zero.
<i>alpha</i>	REAL for <i>sgemv</i> DOUBLE PRECISION for <i>dgemv</i> COMPLEX for <i>cgemv</i> DOUBLE COMPLEX for <i>zgemv</i> Specifies the scalar α .
<i>a</i>	REAL for <i>sgemv</i> DOUBLE PRECISION for <i>dgemv</i> COMPLEX for <i>cgemv</i> DOUBLE COMPLEX for <i>zgemv</i> Array, DIMENSION (lda , n). Before entry, the leading m -by- n part of the array a must contain the matrix of coefficients.
<i>lda</i>	INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, m)$.
<i>x</i>	REAL for <i>sgemv</i> DOUBLE PRECISION for <i>dgemv</i> COMPLEX for <i>cgemv</i>

	DOUBLE COMPLEX for zgemv Array, DIMENSION at least $(1+(n-1)*abs(incx))$ when $trans = 'N'$ or $'n'$ and at least $(1+(m-1)*abs(incx))$ otherwise. Before entry, the incremented array x must contain the vector x .
<i>incx</i>	INTEGER. Specifies the increment for the elements of x . The value of <i>incx</i> must not be zero.
<i>beta</i>	REAL for sgemv DOUBLE PRECISION for dgemv COMPLEX for cgemv DOUBLE COMPLEX for zgemv Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then y need not be set on input.
y	REAL for sgemv DOUBLE PRECISION for dgemv COMPLEX for cgemv DOUBLE COMPLEX for zgemv Array, DIMENSION at least $(1+(m-1)*abs(incy))$ when $trans = 'N'$ or $'n'$ and at least $(1+(n-1)*abs(incy))$ otherwise. Before entry with non-zero <i>beta</i> , the incremented array y must contain the vector y .
<i>incy</i>	INTEGER. Specifies the increment for the elements of y . The value of <i>incy</i> must not be zero.

Output Parameters

y Updated vector y .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gemv` interface are the following:

<i>a</i>	Holds the matrix A of size (m,n) .
<i>x</i>	Holds the vector with the number of elements rx where $rx = n$ if $trans = 'N'$, $rx = m$ otherwise.

<i>y</i>	Holds the vector with the number of elements <i>ry</i> where <i>ry</i> = <i>m</i> if <i>trans</i> = 'N', <i>ry</i> = <i>n</i> otherwise.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?ger

Performs a rank-1 update of a general matrix.

Syntax

FORTRAN 77:

```
call sger(m, n, alpha, x, incx, y, incy, a, lda)
```

```
call dger(m, n, alpha, x, incx, y, incy, a, lda)
```

Fortran 95:

```
call ger(a, x, y [,alpha])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?ger routines perform a matrix-vector operation defined as

$$A := \alpha * x * y' + A,$$

where:

alpha is a scalar,

x is an *m*-element vector,

y is an *n*-element vector,

A is an *m*-by-*n* general matrix.

Input Parameters

<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero.
----------	--

<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>a</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <i>sger</i> DOUBLE PRECISION for <i>dger</i> Specifies the scalar <i>alpha</i> .
<i>x</i>	REAL for <i>sger</i> DOUBLE PRECISION for <i>dger</i> Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>m</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	REAL for <i>sger</i> DOUBLE PRECISION for <i>dger</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.
<i>a</i>	REAL for <i>sger</i> DOUBLE PRECISION for <i>dger</i> Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix of coefficients.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, m)$.

Output Parameters

a Overwritten by the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ger* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m,n</i>).
<i>x</i>	Holds the vector with the number of elements <i>m</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .
<i>alpha</i>	The default value is 1.

?gerc

Performs a rank-1 update (conjugated) of a general matrix.

Syntax

FORTRAN 77:

```
call cgerc(m, n, alpha, x, incx, y, incy, a, lda)
```

```
call zgerc(m, n, alpha, x, incx, y, incy, a, lda)
```

Fortran 95:

```
call gerc(a, x, y [,alpha])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?gerc` routines perform a matrix-vector operation defined as

$$A := \alpha * x * \text{conjg}(y') + A,$$

where:

alpha is a scalar,

x is an *m*-element vector,

y is an *n*-element vector,

A is an *m*-by-*n* matrix.

Input Parameters

<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>A</i> .

	The value of n must be at least zero.
<i>alpha</i>	COMPLEX for <i>cgerc</i> DOUBLE COMPLEX for <i>zgerc</i> Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for <i>cgerc</i> DOUBLE COMPLEX for <i>zgerc</i> Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the m -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	COMPLEX for <i>cgerc</i> DOUBLE COMPLEX for <i>zgerc</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the n -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.
<i>a</i>	COMPLEX for <i>cgerc</i> DOUBLE COMPLEX for <i>zgerc</i> Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry, the leading m -by- n part of the array <i>a</i> must contain the matrix of coefficients.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, m)$.

Output Parameters

a Overwritten by the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gerc* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m,n) .
<i>x</i>	Holds the vector with the number of elements <i>m</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .
<i>alpha</i>	The default value is 1.

?geru

Performs a rank-1 update (unconjugated) of a general matrix.

Syntax

FORTRAN 77:

```
call cgeru(m, n, alpha, x, incx, y, incy, a, lda)
```

```
call zgeru(m, n, alpha, x, incx, y, incy, a, lda)
```

Fortran 95:

```
call geru(a, x, y [,alpha])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?geru routines perform a matrix-vector operation defined as

$$A := \alpha * x * y^T + A,$$

where:

alpha is a scalar,

x is an *m*-element vector,

y is an *n*-element vector,

A is an *m*-by-*n* matrix.

Input Parameters

<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>A</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>A</i> .

	The value of n must be at least zero.
<i>alpha</i>	COMPLEX for <i>cgeru</i> DOUBLE COMPLEX for <i>zgeru</i> Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for <i>cgeru</i> DOUBLE COMPLEX for <i>zgeru</i> Array, DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>m</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	COMPLEX for <i>cgeru</i> DOUBLE COMPLEX for <i>zgeru</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.
<i>a</i>	COMPLEX for <i>cgeru</i> DOUBLE COMPLEX for <i>zgeru</i> Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix of coefficients.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, m)$.

Output Parameters

a Overwritten by the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *geru* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m,n) .
<i>x</i>	Holds the vector with the number of elements <i>m</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .
<i>alpha</i>	The default value is 1.

?hbmV

Computes a matrix-vector product using a Hermitian band matrix.

Syntax

FORTRAN 77:

```
call chbmV(uplo, n, k, alpha, a, lda, x, incx, beta, y, incy)
call zhbmV(uplo, n, k, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call hbmV(a, x, y [,uplo][,alpha] [,beta])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?hbmV routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

where:

alpha and *beta* are scalars,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* Hermitian band matrix, with *k* super-diagonals.

Input Parameters

uplo CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian band matrix *A* is used: If *uplo* = 'U' or 'u', then the upper triangular part of the matrix *A* is used.

	If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. Specifies the number of super-diagonals of the matrix <i>A</i> . The value of <i>k</i> must satisfy $0 \leq k$.
<i>alpha</i>	COMPLEX for <i>chbmv</i> DOUBLE COMPLEX for <i>zhbmv</i> Specifies the scalar <i>alpha</i> .
<i>a</i>	COMPLEX for <i>chbmv</i> DOUBLE COMPLEX for <i>zhbmv</i> Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading (<i>k</i> + 1) by <i>n</i> part of the array <i>a</i> must contain the upper triangular band part of the Hermitian matrix. The matrix must be supplied column-by-column, with the leading diagonal of the matrix in row (<i>k</i> + 1) of the array, the first super-diagonal starting at position 2 in row <i>k</i> , and so on. The top left <i>k</i> by <i>k</i> triangle of the array <i>a</i> is not referenced. The following program segment transfers the upper triangular part of a Hermitian band matrix from conventional full matrix storage to band storage: <pre> do 20, j = 1, n m = k + 1 - j do 10, i = max(1, j - k), j a(m + i, j) = matrix(i, j) 10 continue 20 continue </pre> Before entry with <i>uplo</i> = 'L' or 'l', the leading (<i>k</i> + 1) by <i>n</i> part of the array <i>a</i> must contain the lower triangular band part of the Hermitian matrix, supplied column-by-column, with the leading diagonal of the matrix

in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array a is not referenced.

The following program segment transfers the lower triangular part of a Hermitian band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
    m = 1 - j
    do 10, i = j, min( n, j + k )
        a( m + i, j ) = matrix( i, j )
    10 continue
20 continue

```

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

<i>lda</i>	INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. The value of <i>lda</i> must be at least $(k + 1)$.
<i>x</i>	COMPLEX for <code>chbmv</code> DOUBLE COMPLEX for <code>zhbmv</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array x must contain the vector x .
<i>incx</i>	INTEGER. Specifies the increment for the elements of x . The value of <i>incx</i> must not be zero.
<i>beta</i>	COMPLEX for <code>chbmv</code> DOUBLE COMPLEX for <code>zhbmv</code> Specifies the scalar <i>beta</i> .
<i>y</i>	COMPLEX for <code>chbmv</code> DOUBLE COMPLEX for <code>zhbmv</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array y must contain the vector y .
<i>incy</i>	INTEGER. Specifies the increment for the elements of y . The value of <i>incy</i> must not be zero.

Output Parameters

y Overwritten by the updated vector *y*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbmV` interface are the following:

<i>a</i>	Holds the array <i>a</i> of size $(k+1, n)$.
<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?hemv

Computes a matrix-vector product using a Hermitian matrix.

Syntax

FORTRAN 77:

```
call chemv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
call zhemv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call hemv(a, x, y [,uplo][,alpha] [,beta])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?hemv` routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

where:

α and β are scalars,

x and y are n -element vectors,

A is an n -by- n Hermitian matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array a is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular of the array a is used. If <i>uplo</i> = 'L' or 'l', then the low triangular of the array a is used.
<i>n</i>	INTEGER. Specifies the order of the matrix A . The value of n must be at least zero.
<i>alpha</i>	COMPLEX for chemv DOUBLE COMPLEX for zhemv Specifies the scalar α .
<i>a</i>	COMPLEX for chemv DOUBLE COMPLEX for zhemv Array, DIMENSION (lda , n). Before entry with <i>uplo</i> = 'U' or 'u', the leading n -by- n upper triangular part of the array a must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of a is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading n -by- n lower triangular part of the array a must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of a is not referenced. The imaginary parts of the diagonal elements need not be set and are assumed to be zero.
<i>lda</i>	INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, n)$.
<i>x</i>	COMPLEX for chemv DOUBLE COMPLEX for zhemv

	Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the n -element vector x .
<i>incx</i>	INTEGER. Specifies the increment for the elements of x . The value of <i>incx</i> must not be zero.
<i>beta</i>	COMPLEX for chemv DOUBLE COMPLEX for zhemv Specifies the scalar <i>beta</i> . When <i>beta</i> is supplied as zero then y need not be set on input.
y	COMPLEX for chemv DOUBLE COMPLEX for zhemv Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array y must contain the n -element vector y .
<i>incy</i>	INTEGER. Specifies the increment for the elements of y . The value of <i>incy</i> must not be zero.

Output Parameters

y	Overwritten by the updated vector y .
-----	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine hemv interface are the following:

<i>a</i>	Holds the matrix A of size (n,n) .
x	Holds the vector with the number of elements n .
y	Holds the vector with the number of elements n .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?her

Performs a rank-1 update of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cher(uplo, n, alpha, x, incx, a, lda)
call zher(uplo, n, alpha, x, incx, a, lda)
```

Fortran 95:

```
call her(a, x [,uplo] [, alpha])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?her routines perform a matrix-vector operation defined as

$$A := \alpha * x * \text{conjg}(x') + A,$$

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* Hermitian matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for cher DOUBLE PRECISION for zher Specifies the scalar <i>alpha</i> .

<i>x</i>	<p>COMPLEX for <i>cher</i> DOUBLE COMPLEX for <i>zher</i> Array, dimension at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.</p>
<i>incx</i>	<p>INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.</p>
<i>a</i>	<p>COMPLEX for <i>cher</i> DOUBLE COMPLEX for <i>zher</i> Array, DIMENSION (<i>lda</i>, <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of <i>a</i> is not referenced. The imaginary parts of the diagonal elements need not be set and are assumed to be zero.</p>
<i>lda</i>	<p>INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.</p>

Output Parameters

<i>a</i>	<p>With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated matrix. The imaginary parts of the diagonal elements are set to zero.</p>
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `her` interface are the following:

<code>a</code>	Holds the matrix A of size (n,n) .
<code>x</code>	Holds the vector with the number of elements n .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>alpha</code>	The default value is 1.

?her2

Performs a rank-2 update of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cher2(uplo, n, alpha, x, incx, y, incy, a, lda)
call zher2(uplo, n, alpha, x, incx, y, incy, a, lda)
```

Fortran 95:

```
call her2(a, x, y [,uplo][,alpha])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?her2 routines perform a matrix-vector operation defined as

$$A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A,$$

where:

`alpha` is a scalar,

`x` and `y` are n -element vectors,

`A` is an n -by- n Hermitian matrix.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used.</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular of the array <i>a</i> is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular of the array <i>a</i> is used.</p>
<i>n</i>	<p>INTEGER. Specifies the order of the matrix <i>A</i>. The value of <i>n</i> must be at least zero.</p>
<i>alpha</i>	<p>COMPLEX for <i>cher2</i> DOUBLE COMPLEX for <i>zher2</i> Specifies the scalar <i>alpha</i>.</p>
<i>x</i>	<p>COMPLEX for <i>cher2</i> DOUBLE COMPLEX for <i>zher2</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i>-element vector <i>x</i>.</p>
<i>incx</i>	<p>INTEGER. Specifies the increment for the elements of <i>x</i>. The value of <i>incx</i> must not be zero.</p>
<i>y</i>	<p>COMPLEX for <i>cher2</i> DOUBLE COMPLEX for <i>zher2</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i>-element vector <i>y</i>.</p>
<i>incy</i>	<p>INTEGER. Specifies the increment for the elements of <i>y</i>. The value of <i>incy</i> must not be zero.</p>
<i>a</i>	<p>COMPLEX for <i>cher2</i> DOUBLE COMPLEX for <i>zher2</i> Array, DIMENSION (<i>lda</i>, <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>a</i> is not referenced.</p>

Before entry with $uplo = 'L'$ or $'l'$, the leading n -by- n lower triangular part of the array a must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of a is not referenced.

The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

lda

INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, n)$.

Output Parameters

a

With $uplo = 'U'$ or $'u'$, the upper triangular part of the array a is overwritten by the upper triangular part of the updated matrix.

With $uplo = 'L'$ or $'l'$, the lower triangular part of the array a is overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `her2` interface are the following:

a	Holds the matrix A of size (n,n) .
x	Holds the vector with the number of elements n .
y	Holds the vector with the number of elements n .
$uplo$	Must be $'U'$ or $'L'$. The default value is $'U'$.
$alpha$	The default value is 1.

?hpmv

Computes a matrix-vector product using a Hermitian packed matrix.

Syntax

FORTRAN 77:

```
call chpmv(uplo, n, alpha, ap, x, incx, beta, y, incy)
call zhpmv(uplo, n, alpha, ap, x, incx, beta, y, incy)
```

Fortran 95:

```
call hpmv(ap, x, y [,uplo][,alpha] [,beta])
```

Description

This routine is declared in `mk1_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mk1_blas.h` for C interface.

The ?hpmv routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

where:

alpha and *beta* are scalars,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* Hermitian matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for <code>chpmv</code>

	DOUBLE COMPLEX for zhpmv Specifies the scalar <i>alpha</i> .
<i>ap</i>	COMPLEX for chpmv DOUBLE COMPLEX for zhpmv Array, DIMENSION at least $((n*(n + 1))/2)$. Before entry with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>a</i> (1, 1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>a</i> (1, 2) and <i>a</i> (2, 2) respectively, and so on. Before entry with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>a</i> (1, 1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>a</i> (2, 1) and <i>a</i> (3, 1) respectively, and so on. The imaginary parts of the diagonal elements need not be set and are assumed to be zero.
<i>x</i>	COMPLEX for chpmv DOUBLE PRECISION COMPLEX for zhpmv Array, DIMENSION at least $(1 + (n - 1)*abs(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>beta</i>	COMPLEX for chpmv DOUBLE COMPLEX for zhpmv Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero then <i>y</i> need not be set on input.
<i>y</i>	COMPLEX for chpmv DOUBLE COMPLEX for zhpmv Array, DIMENSION at least $(1 + (n - 1)*abs(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.

Output Parameters

y Overwritten by the updated vector y .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpmv` interface are the following:

ap	Holds the array ap of size $(n*(n+1)/2)$.
x	Holds the vector with the number of elements n .
y	Holds the vector with the number of elements n .
$uplo$	Must be 'U' or 'L'. The default value is 'U'.
$alpha$	The default value is 1.
$beta$	The default value is 0.

?hpr

Performs a rank-1 update of a Hermitian packed matrix.

Syntax

FORTRAN 77:

```
call chpr(uplo, n, alpha, x, incx, ap)
call zhpr(uplo, n, alpha, x, incx, ap)
```

Fortran 95:

```
call hpr(ap, x [,uplo] [, alpha])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?hpr` routines perform a matrix-vector operation defined as

$$A := \alpha * x * \text{conjg}(x') + A,$$

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* Hermitian matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <i>chpr</i> DOUBLE PRECISION for <i>zhpr</i> Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for <i>chpr</i> DOUBLE COMPLEX for <i>zhpr</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . <i>incx</i> must not be zero.
<i>ap</i>	COMPLEX for <i>chpr</i> DOUBLE COMPLEX for <i>zhpr</i> Array, DIMENSION at least $((n * (n + 1)) / 2)$. Before entry with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>a</i> (1, 1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>a</i> (1, 2) and <i>a</i> (2, 2) respectively, and so on.

Before entry with `uplo = 'L' or 'l'`, the array `ap` must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that `ap(1)` contains `a(1, 1)`, `ap(2)` and `ap(3)` contain `a(2, 1)` and `a(3, 1)` respectively, and so on. The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

Output Parameters

`ap` With `uplo = 'U' or 'u'`, overwritten by the upper triangular part of the updated matrix. With `uplo = 'L' or 'l'`, overwritten by the lower triangular part of the updated matrix. The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpr` interface are the following:

<code>ap</code>	Holds the array <code>ap</code> of size $(n*(n+1)/2)$.
<code>x</code>	Holds the vector with the number of elements <code>n</code> .
<code>uplo</code>	Must be <code>'U'</code> or <code>'L'</code> . The default value is <code>'U'</code> .
<code>alpha</code>	The default value is 1.

?hpr2

Performs a rank-2 update of a Hermitian packed matrix.

Syntax

FORTRAN 77:

```
call chpr2(uplo, n, alpha, x, incx, y, incy, ap)
call zhpr2(uplo, n, alpha, x, incx, y, incy, ap)
```

Fortran 95:

```
call hpr2(ap, x, y [,uplo][,alpha])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?hpr2` routines perform a matrix-vector operation defined as

$$A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A,$$

where:

alpha is a scalar,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* Hermitian matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	COMPLEX for <code>chpr2</code> DOUBLE COMPLEX for <code>zhpr2</code> Specifies the scalar <i>alpha</i> .
<i>x</i>	COMPLEX for <code>chpr2</code> DOUBLE COMPLEX for <code>zhpr2</code> Array, dimension at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	COMPLEX for <code>chpr2</code>

DOUBLE COMPLEX for zhpr2
 Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incy))$.
 Before entry, the incremented array y must contain the n -element vector y .

incy INTEGER. Specifies the increment for the elements of y .
 The value of *incy* must not be zero.

ap COMPLEX for chpr2
 DOUBLE COMPLEX for zhpr2
 Array, DIMENSION at least $((n * (n + 1)) / 2)$. Before entry with *uplo* = 'U' or 'u', the array *ap* must contain the upper triangular part of the Hermitian matrix packed sequentially, column-by-column, so that *ap*(1) contains $a(1,1)$, *ap*(2) and *ap*(3) contain $a(1,2)$ and $a(2,2)$ respectively, and so on.
 Before entry with *uplo* = 'L' or 'l', the array *ap* must contain the lower triangular part of the Hermitian matrix packed sequentially, column-by-column, so that *ap*(1) contains $a(1,1)$, *ap*(2) and *ap*(3) contain $a(2,1)$ and $a(3,1)$ respectively, and so on.
 The imaginary parts of the diagonal elements need not be set and are assumed to be zero.

Output Parameters

ap With *uplo* = 'U' or 'u', overwritten by the upper triangular part of the updated matrix.
 With *uplo* = 'L' or 'l', overwritten by the lower triangular part of the updated matrix.
 The imaginary parts of the diagonal elements need are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpr2` interface are the following:

ap Holds the array *ap* of size $(n * (n + 1) / 2)$.

<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.

?sbmv

Computes a matrix-vector product using a symmetric band matrix.

Syntax

FORTRAN 77:

```
call ssbmv(uplo, n, k, alpha, a, lda, x, incx, beta, y, incy)
call dsbmv(uplo, n, k, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call sbmv(a, x, y [,uplo][,alpha] [,beta])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?sbmv` routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

where:

alpha and *beta* are scalars,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* symmetric band matrix, with *k* super-diagonals.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the band matrix <i>A</i> is used: if <i>uplo</i> = 'U' or 'u' - upper triangular part; if <i>uplo</i> = 'L' or 'l' - low triangular part.
-------------	--

<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>k</i>	INTEGER. Specifies the number of super-diagonals of the matrix <i>A</i> . The value of <i>k</i> must satisfy $0 \leq k$.
<i>alpha</i>	REAL for <i>ssbmv</i> DOUBLE PRECISION for <i>dsbmv</i> Specifies the scalar <i>alpha</i> .
<i>a</i>	REAL for <i>ssbmv</i> DOUBLE PRECISION for <i>dsbmv</i> Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading (<i>k</i> + 1) by <i>n</i> part of the array <i>a</i> must contain the upper triangular band part of the symmetric matrix, supplied column-by-column, with the leading diagonal of the matrix in row (<i>k</i> + 1) of the array, the first super-diagonal starting at position 2 in row <i>k</i> , and so on. The top left <i>k</i> by <i>k</i> triangle of the array <i>a</i> is not referenced. The following program segment transfers the upper triangular part of a symmetric band matrix from conventional full matrix storage to band storage: <pre> do 20, j = 1, n m = k + 1 - j do 10, i = max(1, j - k), j a(m + i, j) = matrix(i, j) 10 continue 20 continue </pre> Before entry with <i>uplo</i> = 'L' or 'l', the leading (<i>k</i> + 1) by <i>n</i> part of the array <i>a</i> must contain the lower triangular band part of the symmetric matrix, supplied column-by-column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right <i>k</i> by <i>k</i> triangle of the array <i>a</i> is not referenced.

The following program segment transfers the lower triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
    m = 1 - j
    do 10, i = j, min( n, j + k )
        a( m + i, j ) = matrix( i, j )
    10 continue
20 continue

```

<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $(k + 1)$.
<i>x</i>	REAL for <i>ssbmv</i> DOUBLE PRECISION for <i>dsbmv</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>beta</i>	REAL for <i>ssbmv</i> DOUBLE PRECISION for <i>dsbmv</i> Specifies the scalar <i>beta</i> .
<i>y</i>	REAL for <i>ssbmv</i> DOUBLE PRECISION for <i>dsbmv</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbmv` interface are the following:

<i>a</i>	Holds the array <i>a</i> of size $(k+1, n)$.
<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?spmv

Computes a matrix-vector product using a symmetric packed matrix.

Syntax

FORTRAN 77:

```
call sspmv(uplo, n, alpha, ap, x, incx, beta, y, incy)
call dspmv(uplo, n, alpha, ap, x, incx, beta, y, incy)
```

Fortran 95:

```
call spmv(ap, x, y [,uplo][,alpha] [,beta])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?spmv` routines perform a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y,$$

where:

alpha and *beta* are scalars,

x and *y* are *n*-element vectors,

A is an n -by- n symmetric matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array ap.</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix A is supplied in the packed array ap.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix A is supplied in the packed array ap.</p>
<i>n</i>	<p>INTEGER. Specifies the order of the matrix a. The value of n must be at least zero.</p>
<i>alpha</i>	<p>REAL for <i>sspmv</i> DOUBLE PRECISION for <i>dspmv</i></p> <p>Specifies the scalar <i>alpha</i>.</p>
<i>ap</i>	<p>REAL for <i>sspmv</i> DOUBLE PRECISION for <i>dspmv</i></p> <p>Array, DIMENSION at least $((n*(n + 1))/2)$. Before entry with <i>uplo</i> = 'U' or 'u', the array ap must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that $ap(1)$ contains $a(1,1)$, $ap(2)$ and $ap(3)$ contain $a(1,2)$ and $a(2, 2)$ respectively, and so on. Before entry with <i>uplo</i> = 'L' or 'l', the array ap must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that $ap(1)$ contains $a(1,1)$, $ap(2)$ and $ap(3)$ contain $a(2,1)$ and $a(3,1)$ respectively, and so on.</p>
<i>x</i>	<p>REAL for <i>sspmv</i> DOUBLE PRECISION for <i>dspmv</i></p> <p>Array, DIMENSION at least $(1 + (n - 1)*abs(incx))$. Before entry, the incremented array x must contain the n-element vector x.</p>
<i>incx</i>	<p>INTEGER. Specifies the increment for the elements of x. The value of <i>incx</i> must not be zero.</p>
<i>beta</i>	<p>REAL for <i>sspmv</i> DOUBLE PRECISION for <i>dspmv</i></p>

	Specifies the scalar <i>beta</i> . When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input.
<i>y</i>	REAL for <i>sspmv</i> DOUBLE PRECISION for <i>dspmv</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *spmv* interface are the following:

<i>ap</i>	Holds the array <i>ap</i> of size $(n * (n + 1) / 2)$.
<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?spr

Performs a rank-1 update of a symmetric packed matrix.

Syntax

FORTRAN 77:

```
call sspr(uplo, n, alpha, x, incx, ap)
```

```
call dspr(uplo, n, alpha, x, incx, ap)
```

Fortran 95:

```
call spr(ap, x [,uplo] [, alpha])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?spr` routines perform a matrix-vector operation defined as

$$a := \alpha * x * x' + A,$$

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* symmetric matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <code>sspr</code> DOUBLE PRECISION for <code>dspr</code> Specifies the scalar <i>alpha</i> .
<i>x</i>	REAL for <code>sspr</code> DOUBLE PRECISION for <code>dspr</code> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.

ap REAL for *sspr*
 DOUBLE PRECISION for *dspr*
 Array, DIMENSION at least $((n*(n + 1))/2)$. Before entry with *uplo* = 'U' or 'u', the array *ap* must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that *ap*(1) contains $a(1,1)$, *ap*(2) and *ap*(3) contain $a(1,2)$ and $a(2,2)$ respectively, and so on. Before entry with *uplo* = 'L' or 'l', the array *ap* must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that *ap*(1) contains $a(1,1)$, *ap*(2) and *ap*(3) contain $a(2,1)$ and $a(3,1)$ respectively, and so on.

Output Parameters

ap With *uplo* = 'U' or 'u', overwritten by the upper triangular part of the updated matrix.
 With *uplo* = 'L' or 'l', overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *spr* interface are the following:

ap Holds the array *ap* of size $(n*(n+1)/2)$.
x Holds the vector with the number of elements *n*.
uplo Must be 'U' or 'L'. The default value is 'U'.
alpha The default value is 1.

?spr2

Performs a rank-2 update of a symmetric packed matrix.

Syntax

FORTRAN 77:

```
call sspr2(uplo, n, alpha, x, incx, y, incy, ap)
call dspr2(uplo, n, alpha, x, incx, y, incy, ap)
```

Fortran 95:

```
call spr2(ap, x, y [,uplo][,alpha])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?spr2` routines perform a matrix-vector operation defined as

$$A := \alpha * x * y' + \alpha * y * x' + A,$$

where:

alpha is a scalar,

x and *y* are *n*-element vectors,

A is an *n*-by-*n* symmetric matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> . If <i>uplo</i> = 'L' or 'l', then the low triangular part of the matrix <i>A</i> is supplied in the packed array <i>ap</i> .
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <code>sspr2</code>

	DOUBLE PRECISION for dspr2 Specifies the scalar <i>alpha</i> .
<i>x</i>	REAL for sspr2 DOUBLE PRECISION for dspr2 Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	REAL for sspr2 DOUBLE PRECISION for dspr2 Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.
<i>ap</i>	REAL for sspr2 DOUBLE PRECISION for dspr2 Array, DIMENSION at least $((n * (n + 1)) / 2)$. Before entry with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>a</i> (1,1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>a</i> (1,2) and <i>a</i> (2,2) respectively, and so on. Before entry with <i>uplo</i> = 'L' or 'l', the array <i>ap</i> must contain the lower triangular part of the symmetric matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains <i>a</i> (1,1), <i>ap</i> (2) and <i>ap</i> (3) contain <i>a</i> (2,1) and <i>a</i> (3,1) respectively, and so on.

Output Parameters

<i>ap</i>	With <i>uplo</i> = 'U' or 'u', overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = 'L' or 'l', overwritten by the lower triangular part of the updated matrix.
-----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spr2` interface are the following:

<code>ap</code>	Holds the array <code>ap</code> of size $(n*(n+1))/2$.
<code>x</code>	Holds the vector with the number of elements <code>n</code> .
<code>y</code>	Holds the vector with the number of elements <code>n</code> .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>alpha</code>	The default value is 1.

?symv

Computes a matrix-vector product for a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssymv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
call dsymv(uplo, n, alpha, a, lda, x, incx, beta, y, incy)
```

Fortran 95:

```
call symv(a, x, y [,uplo][,alpha] [,beta])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?symv` routines perform a matrix-vector operation defined as

$$y := \alpha A x + \beta y,$$

where:

`alpha` and `beta` are scalars,

`x` and `y` are `n`-element vectors,

A is an n -by- n symmetric matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array a is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array a is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array a is used.
<i>n</i>	INTEGER. Specifies the order of the matrix a . The value of n must be at least zero.
<i>alpha</i>	REAL for <i>ssymv</i> DOUBLE PRECISION for <i>dsymv</i> Specifies the scalar <i>alpha</i> .
<i>a</i>	REAL for <i>ssymv</i> DOUBLE PRECISION for <i>dsymv</i> Array, DIMENSION (lda, n). Before entry with <i>uplo</i> = 'U' or 'u', the leading n -by- n upper triangular part of the array a must contain the upper triangular part of the symmetric matrix A and the strictly lower triangular part of a is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading n -by- n lower triangular part of the array a must contain the lower triangular part of the symmetric matrix A and the strictly upper triangular part of a is not referenced.
<i>lda</i>	INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. The value of lda must be at least $\max(1, n)$.
<i>x</i>	REAL for <i>ssymv</i> DOUBLE PRECISION for <i>dsymv</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array x must contain the n -element vector x .
<i>incx</i>	INTEGER. Specifies the increment for the elements of x . The value of <i>incx</i> must not be zero.
<i>beta</i>	REAL for <i>ssymv</i> DOUBLE PRECISION for <i>dsymv</i>

	Specifies the scalar <i>beta</i> . When <i>beta</i> is supplied as zero, then <i>y</i> need not be set on input.
<i>y</i>	REAL for <i>ssymv</i> DOUBLE PRECISION for <i>dsymv</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\textit{incy}))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *symv* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n,n) .
<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>y</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?syr

Performs a rank-1 update of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyr(uplo, n, alpha, x, incx, a, lda)
call dsyr(uplo, n, alpha, x, incx, a, lda)
```

Fortran 95:

```
call syr(a, x [,uplo] [, alpha])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?syr` routines perform a matrix-vector operation defined as

$$A := \alpha * x * x' + A,$$

where:

alpha is a real scalar,

x is an *n*-element vector,

A is an *n*-by-*n* symmetric matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <i>ssyr</i> DOUBLE PRECISION for <i>dsyr</i> Specifies the scalar <i>alpha</i> .
<i>x</i>	REAL for <i>ssyr</i> DOUBLE PRECISION for <i>dsyr</i> Array, DIMENSION at least $(1 + (n-1)*abs(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>a</i>	REAL for <i>ssyr</i> DOUBLE PRECISION for <i>dsyr</i>

Array, DIMENSION (*lda*, *n*).

Before entry with *uplo* = 'U' or 'u', the leading *n*-by-*n* upper triangular part of the array *a* must contain the upper triangular part of the symmetric matrix *A* and the strictly lower triangular part of *a* is not referenced.

Before entry with *uplo* = 'L' or 'l', the leading *n*-by-*n* lower triangular part of the array *a* must contain the lower triangular part of the symmetric matrix *A* and the strictly upper triangular part of *a* is not referenced.

lda INTEGER. Specifies the first dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least $\max(1, n)$.

Output Parameters

a With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated matrix.
With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *syr* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.

?syr2

Performs a rank-2 update of symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyr2(uplo, n, alpha, x, incx, y, incy, a, lda)
call dsyr2(uplo, n, alpha, x, incx, y, incy, a, lda)
```

Fortran 95:

```
call syr2(a, x, y [,uplo][,alpha])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?syr2 routines perform a matrix-vector operation defined as

$$A := \alpha x x^T + \alpha y y^T + A,$$

where:

α is a scalar,

x and y are n -element vectors,

A is an n -by- n symmetric matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>a</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>a</i> is used.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>A</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <code>ssyr2</code> DOUBLE PRECISION for <code>dsyr2</code> Specifies the scalar <i>alpha</i> .

<i>x</i>	REAL for <i>ssyr2</i> DOUBLE PRECISION for <i>dsyr2</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.
<i>y</i>	REAL for <i>ssyr2</i> DOUBLE PRECISION for <i>dsyr2</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incy))$. Before entry, the incremented array <i>y</i> must contain the <i>n</i> -element vector <i>y</i> .
<i>incy</i>	INTEGER. Specifies the increment for the elements of <i>y</i> . The value of <i>incy</i> must not be zero.
<i>a</i>	REAL for <i>ssyr2</i> DOUBLE PRECISION for <i>dsyr2</i> Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated matrix.
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syx2` interface are the following:

<code>a</code>	Holds the matrix A of size (n,n) .
<code>x</code>	Holds the vector x of length n .
<code>y</code>	Holds the vector y of length n .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>alpha</code>	The default value is 1.

?tbmv

Computes a matrix-vector product using a triangular band matrix.

Syntax

FORTRAN 77:

```
call stbmv(uplo, trans, diag, n, k, a, lda, x, incx)
call dtbmv(uplo, trans, diag, n, k, a, lda, x, incx)
call ctbmv(uplo, trans, diag, n, k, a, lda, x, incx)
call ztbmv(uplo, trans, diag, n, k, a, lda, x, incx)
```

Fortran 95:

```
call tbmv(a, x [,uplo] [, trans] [,diag])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?tbmv` routines perform one of the matrix-vector operations defined as

$x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$,

where:

x is an n -element vector,

A is an n -by- n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is an upper or lower triangular matrix: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $x := A*x$; if <i>trans</i> = 'T' or 't', then $x := A'*x$; if <i>trans</i> = 'C' or 'c', then $x := \text{conjg}(A)*x$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix A . The value of n must be at least zero.
<i>k</i>	INTEGER. On entry with <i>uplo</i> = 'U' or 'u', k specifies the number of super-diagonals of the matrix A . On entry with <i>uplo</i> = 'L' or 'l', k specifies the number of sub-diagonals of the matrix a . The value of k must satisfy $0 \leq k$.
<i>a</i>	REAL for stbmv DOUBLE PRECISION for dtbmv COMPLEX for ctbmv DOUBLE COMPLEX for ztbmv Array, DIMENSION (lda , n). Before entry with <i>uplo</i> = 'U' or 'u', the leading $(k + 1)$ by n part of the array a must contain the upper triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle

of the array a is not referenced. The following program segment transfers an upper triangular band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
    m = k + 1 - j
do 10, i = max(1, j - k), j
    a(m + i, j) = matrix(i, j)
10 continue
20 continue

```

Before entry with $uplo = 'L'$ or $'l'$, the leading $(k + 1)$ by n part of the array a must contain the lower triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array a is not referenced. The following program segment transfers a lower triangular band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
    m = 1 - j
    do 10, i = j, min(n, j + k)
        a(m + i, j) = matrix (i, j)
10 continue
20 continue

```

Note that when $diag = 'U'$ or $'u'$, the elements of the array a corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

lda

INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. The value of lda must be at least $(k + 1)$.

x

REAL for stbmv
 DOUBLE PRECISION for dtbmv
 COMPLEX for ctbmv

DOUBLE COMPLEX for `ztbmv`
Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(incx))$.
Before entry, the incremented array `x` must contain the n -element vector `x`.
`incx` INTEGER. Specifies the increment for the elements of `x`.
The value of `incx` must not be zero.

Output Parameters

`x` Overwritten with the transformed vector `x`.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `t_bmv` interface are the following:

<code>a</code>	Holds the array <code>a</code> of size $(k+1, n)$.
<code>x</code>	Holds the vector with the number of elements n .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>trans</code>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<code>diag</code>	Must be 'N' or 'U'. The default value is 'N'.

?tbsv

Solves a system of linear equations whose coefficients are in a triangular band matrix.

Syntax

FORTRAN 77:

```
call stbsv(uplo, trans, diag, n, k, a, lda, x, incx)
call dtbsv(uplo, trans, diag, n, k, a, lda, x, incx)
call ctbsv(uplo, trans, diag, n, k, a, lda, x, incx)
call ztbsv(uplo, trans, diag, n, k, a, lda, x, incx)
```

Fortran 95:

```
call tbsv(a, x [,uplo] [, trans] [,diag])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?tbsv` routines solve one of the following systems of equations:

$$A*x = b, \text{ or } A'*x = b, \text{ or } \text{conjg}(A')*x = b,$$

where:

b and x are n -element vectors,

A is an n -by- n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

The routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is an upper or lower triangular matrix: if <i>uplo</i> = 'U' or 'u' the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the system of equations: if <i>trans</i> = 'N' or 'n', then $A*x = b$; if <i>trans</i> = 'T' or 't', then $A'*x = b$; if <i>trans</i> = 'C' or 'c', then $\text{conjg}(A')*x = b$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix A . The value of n must be at least zero.
<i>k</i>	INTEGER. On entry with <i>uplo</i> = 'U' or 'u', k specifies the number of super-diagonals of the matrix A . On entry with <i>uplo</i> = 'L' or 'l', k specifies the number of sub-diagonals of the matrix A .

a

The value of k must satisfy $0 \leq k$.

REAL for *stbsv*
 DOUBLE PRECISION for *dtbsv*
 COMPLEX for *ctbsv*
 DOUBLE COMPLEX for *ztbsv*
 Array, DIMENSION (*lda*, *n*).

Before entry with *uplo* = 'U' or 'u', the leading $(k + 1)$ by n part of the array *a* must contain the upper triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array *a* is not referenced.

The following program segment transfers an upper triangular band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
  m = k + 1 - j
  do 10, i = max(1, j - k), j1
    a(m + i, j) = matrix (i, j)
  10 continue
20 continue

```

Before entry with *uplo* = 'L' or 'l', the leading $(k + 1)$ by n part of the array *a* must contain the lower triangular band part of the matrix of coefficients, supplied column-by-column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array *a* is not referenced.

The following program segment transfers a lower triangular band matrix from conventional full matrix storage to band storage:

```

do 20, j = 1, n
  m = 1 - j
  do 10, i = j, min(n, j + k)
    a(m + i, j) = matrix (i, j)
  10 continue
20 continue

```

When *diag* = 'U' or 'u', the elements of the array *a* corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity.

lda INTEGER. Specifies the first dimension of *a* as declared in the calling (sub)program. The value of *lda* must be at least (*k* + 1).

x REAL for *stbsv*
DOUBLE PRECISION for *dtbsv*
COMPLEX for *ctbsv*
DOUBLE COMPLEX for *ztbsv*
Array, DIMENSION at least (1 + (n - 1)*abs(*incx*)). Before entry, the incremented array *x* must contain the *n*-element right-hand side vector *b*.

incx INTEGER. Specifies the increment for the elements of *x*. The value of *incx* must not be zero.

Output Parameters

x Overwritten with the solution vector *x*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *tbsv* interface are the following:

a Holds the array *a* of size (*k*+1, *n*).

<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

?tpmv

Computes a matrix-vector product using a triangular packed matrix.

Syntax

FORTRAN 77:

```
call stpmv(uplo, trans, diag, n, ap, x, incx)
call dtpmv(uplo, trans, diag, n, ap, x, incx)
call ctpmv(uplo, trans, diag, n, ap, x, incx)
call ztpmv(uplo, trans, diag, n, ap, x, incx)
```

Fortran 95:

```
call tpmv(ap, x [,uplo] [, trans] [,diag])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?tpmv routines perform one of the matrix-vector operations defined as

$$x := A*x, \text{ or } x := A'*x, \text{ or } x := \text{conjg}(A')*x,$$

where:

x is an *n*-element vector,

A is an *n*-by-*n* unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix <i>A</i> is upper or lower triangular:
-------------	--

if *uplo* = 'U' or 'u', then the matrix is upper triangular;
 if *uplo* = 'L' or 'l', then the matrix is low triangular.

trans CHARACTER*1. Specifies the operation:
 if *trans* = 'N' or 'n', then $x := A*x$;
 if *trans* = 'T' or 't', then $x := A'*x$;
 if *trans* = 'C' or 'c', then $x := \text{conjg}(A)*x$.

diag CHARACTER*1. Specifies whether the matrix *A* is unit triangular:
 if *diag* = 'U' or 'u' then the matrix is unit triangular;
 if *diag* = 'N' or 'n', then the matrix is not unit triangular.

n INTEGER. Specifies the order of the matrix *A*. The value of *n* must be at least zero.

ap REAL for *stpmv*
 DOUBLE PRECISION for *dtpmv*
 COMPLEX for *ctpmv*
 DOUBLE COMPLEX for *ztpmv*
 Array, DIMENSION at least $((n*(n+1))/2)$. Before entry with *uplo* = 'U' or 'u', the array *ap* must contain the upper triangular matrix packed sequentially, column-by-column, so that *ap*(1) contains *a*(1,1), *ap*(2) and *ap*(3) contain *a*(1,2) and *a*(2,2) respectively, and so on. Before entry with *uplo* = 'L' or 'l', the array *ap* must contain the lower triangular matrix packed sequentially, column-by-column, so that *ap*(1) contains *a*(1,1), *ap*(2) and *ap*(3) contain *a*(2,1) and *a*(3,1) respectively, and so on. When *diag* = 'U' or 'u', the diagonal elements of *a* are not referenced, but are assumed to be unity.

x REAL for *stpmv*
 DOUBLE PRECISION for *dtpmv*
 COMPLEX for *ctpmv*
 DOUBLE COMPLEX for *ztpmv*
 Array, DIMENSION at least $(1 + (n-1)*\text{abs}(\text{incx}))$. Before entry, the incremented array *x* must contain the *n*-element vector *x*.

incx INTEGER. Specifies the increment for the elements of *x*. The value of *incx* must not be zero.

Output Parameters

x Overwritten with the transformed vector *x*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tpmv` interface are the following:

<i>ap</i>	Holds the array <i>ap</i> of size $(n*(n+1)/2)$.
<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

?tpsv

Solves a system of linear equations whose coefficients are in a triangular packed matrix.

Syntax

FORTRAN 77:

```
call stpsv(uplo, trans, diag, n, ap, x, incx)
call dtpsv(uplo, trans, diag, n, ap, x, incx)
call ctpsv(uplo, trans, diag, n, ap, x, incx)
call ztpsv(uplo, trans, diag, n, ap, x, incx)
```

Fortran 95:

```
call tpsv(ap, x [,uplo] [, trans] [,diag])
```

Description

This routine is declared in `mk1_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mk1_blas.h` for C interface.

The ?t_{psv} routines solve one of the following systems of equations

$A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$,

where:

b and x are n -element vectors,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

This routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the system of equations: if <i>trans</i> = 'N' or 'n', then $A*x = b$; if <i>trans</i> = 'T' or 't', then $A'*x = b$; if <i>trans</i> = 'C' or 'c', then $\text{conjg}(A')*x = b$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix A . The value of n must be at least zero.
<i>ap</i>	REAL for stpsv DOUBLE PRECISION for dtpsv COMPLEX for ctps DOUBLE COMPLEX for ztps Array, DIMENSION at least $((n*(n+1))/2)$. Before entry with <i>uplo</i> = 'U' or 'u', the array <i>ap</i> must contain the upper triangular matrix packed sequentially, column-by-column, so that <i>ap</i> (1) contains $a(1, 1)$, <i>ap</i> (2) and <i>ap</i> (3) contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on.

Before entry with *uplo* = 'L' or 'l', the array *ap* must contain the lower triangular matrix packed sequentially, column-by-column, so that *ap*(1) contains *a*(1, +1), *ap*(2) and *ap*(3) contain *a*(2, +1) and *a*(3, +1) respectively, and so on.

When *diag* = 'U' or 'u', the diagonal elements of *a* are not referenced, but are assumed to be unity.

<i>x</i>	REAL for <i>stpsv</i> DOUBLE PRECISION for <i>dtps</i> COMPLEX for <i>ctps</i> DOUBLE COMPLEX for <i>ztps</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element right-hand side vector <i>b</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten with the solution vector <i>x</i> .
----------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *tps* interface are the following:

<i>ap</i>	Holds the array <i>ap</i> of size $(n * (n + 1) / 2)$.
<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

?trmv

Computes a matrix-vector product using a triangular matrix.

Syntax

FORTRAN 77:

```
call strmv(uplo, trans, diag, n, a, lda, x, incx)
call dtrmv(uplo, trans, diag, n, a, lda, x, incx)
call ctrmv(uplo, trans, diag, n, a, lda, x, incx)
call ztrmv(uplo, trans, diag, n, a, lda, x, incx)
```

Fortran 95:

```
call trmv(a, x [,uplo] [, trans] [,diag])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?trmv routines perform one of the following matrix-vector operations defined as

$x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$,

where:

x is an n -element vector,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $x := A*x$; if <i>trans</i> = 'T' or 't', then $x := A'*x$; if <i>trans</i> = 'C' or 'c', then $x := \text{conjg}(A')*x$.

<i>diag</i>	CHARACTER*1. Specifies whether the matrix <i>a</i> is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix <i>a</i> . The value of <i>n</i> must be at least zero.
<i>a</i>	REAL for <i>strmv</i> DOUBLE PRECISION for <i>dtrmv</i> COMPLEX for <i>ctrmv</i> DOUBLE COMPLEX for <i>ztrmv</i> Array, DIMENSION (<i>lda</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular matrix and the strictly lower triangular part of <i>a</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular matrix and the strictly upper triangular part of <i>a</i> is not referenced. When <i>diag</i> = 'U' or 'u', the diagonal elements of <i>a</i> are not referenced either, but are assumed to be unity.
<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.
<i>x</i>	REAL for <i>strmv</i> DOUBLE PRECISION for <i>dtrmv</i> COMPLEX for <i>ctrmv</i> DOUBLE COMPLEX for <i>ztrmv</i> Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$. Before entry, the incremented array <i>x</i> must contain the <i>n</i> -element vector <i>x</i> .
<i>incx</i>	INTEGER. Specifies the increment for the elements of <i>x</i> . The value of <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten with the transformed vector <i>x</i> .
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trmv` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n,n) .
<i>x</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

?trsv

Solves a system of linear equations whose coefficients are in a triangular matrix.

Syntax

FORTRAN 77:

```
call strsv(uplo, trans, diag, n, a, lda, x, incx)
call dtrsv(uplo, trans, diag, n, a, lda, x, incx)
call ctrsv(uplo, trans, diag, n, a, lda, x, incx)
call ztrsv(uplo, trans, diag, n, a, lda, x, incx)
```

Fortran 95:

```
call trsv(a, x [,uplo] [, trans] [,diag])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?trsv` routines solve one of the systems of equations:

$$A*x = b, \text{ or } A'*x = b, \text{ or } \text{conjg}(A')*x = b,$$

where:

b and x are n -element vectors,

A is an n -by- n unit, or non-unit, upper or lower triangular matrix.

The routine does not test for singularity or near-singularity.

Such tests must be performed before calling this routine.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	CHARACTER*1. Specifies the systems of equations: if <i>trans</i> = 'N' or 'n', then $A*x = b$; if <i>trans</i> = 'T' or 't', then $A'*x = b$; if <i>trans</i> = 'C' or 'c', then $\text{occonjg}(A)*x = b$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	INTEGER. Specifies the order of the matrix A . The value of n must be at least zero.
<i>a</i>	REAL for <i>strsv</i> DOUBLE PRECISION for <i>dtrsv</i> COMPLEX for <i>ctrsv</i> DOUBLE COMPLEX for <i>ztrsv</i> Array, DIMENSION (<i>lda</i> , n). Before entry with <i>uplo</i> = 'U' or 'u', the leading n -by- n upper triangular part of the array a must contain the upper triangular matrix and the strictly lower triangular part of a is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading n -by- n lower triangular part of the array a must contain the lower triangular matrix and the strictly upper triangular part of a is not referenced. When <i>diag</i> = 'U' or 'u', the diagonal elements of a are not referenced either, but are assumed to be unity.
<i>lda</i>	INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.

x REAL for *strsv*
 DOUBLE PRECISION for *dtrsv*
 COMPLEX for *ctrsv*
 DOUBLE COMPLEX for *ztrsv*
 Array, DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{incx}))$.
 Before entry, the incremented array *x* must contain the
n-element right-hand side vector *b*.

incx INTEGER. Specifies the increment for the elements of *x*.
 The value of *incx* must not be zero.

Output Parameters

x Overwritten with the solution vector *x*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *trsv* interface are the following:

a Holds the matrix *a* of size (n,n) .
x Holds the vector with the number of elements *n*.
uplo Must be 'U' or 'L'. The default value is 'U'.
trans Must be 'N', 'C', or 'T'.
 The default value is 'N'.
diag Must be 'N' or 'U'. The default value is 'N'.

BLAS Level 3 Routines

BLAS Level 3 routines perform matrix-matrix operations. [Table 2-3](#) lists the BLAS Level 3 routine groups and the data types associated with them.

Table 2-3 BLAS Level 3 Routine Groups and Their Data Types

Routine Group	Data Types	Description
?gemm	s, d, c, z	Matrix-matrix product of general matrices
?hemm	c, z	Matrix-matrix product of Hermitian matrices

Routine Group	Data Types	Description
?herk	c, z	Rank-k update of Hermitian matrices
?her2k	c, z	Rank-2k update of Hermitian matrices
?symm	s, d, c, z	Matrix-matrix product of symmetric matrices
?syrk	s, d, c, z	Rank-k update of symmetric matrices
?syr2k	s, d, c, z	Rank-2k update of symmetric matrices
?trmm	s, d, c, z	Matrix-matrix product of triangular matrices
?trsm	s, d, c, z	Linear matrix-matrix solution for triangular matrices

Symmetric Multiprocessing Version of Intel® MKL

Many applications spend considerable time for executing BLAS level 3 routines. This time can be scaled by the number of processors available on the system through using the symmetric multiprocessing (SMP) feature built into the Intel MKL Library. The performance enhancements based on the parallel use of the processors are available without any programming effort on your part.

To enhance performance, the library uses the following methods:

- The operation of BLAS level 3 matrix-matrix functions permits to restructure the code in a way which increases the localization of data reference, enhances cache memory use, and reduces the dependency on the memory bus.
- Once the code has been effectively blocked as described above, one of the matrices is distributed across the processors to be multiplied by the second matrix. Such distribution ensures effective cache management which reduces the dependency on the memory bus performance and brings good scaling results.

?gemm

Computes a scalar-matrix-matrix product and adds the result to a scalar-matrix product.

Syntax

FORTRAN 77:

```
call sgemm(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call dgemm(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call cgemm(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call zgemm(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call scgemm(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call dzgemm(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call gemm(a, b, c [,transa][,transb] [,alpha][,beta])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?gemm routines perform a matrix-matrix operation with general matrices. The operation is defined as

$$C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C,$$

where:

$\text{op}(x)$ is one of $\text{op}(x) = x$, or $\text{op}(x) = x'$, or $\text{op}(x) = \text{conjg}(x')$,

α and β are scalars,

A , B and C are matrices:

$\text{op}(A)$ is an m -by- k matrix,

$\text{op}(B)$ is a k -by- n matrix,

C is an m -by- n matrix.

See also [?gemm3m](#), BLAS-like extension routines, that use matrix multiplication for similar matrix-matrix operations.

Input Parameters

<i>transa</i>	<p>CHARACTER*1. Specifies the form of $\text{op}(A)$ used in the matrix multiplication:</p> <p>if <i>transa</i> = 'N' or 'n', then $\text{op}(A) = A$;</p> <p>if <i>transa</i> = 'T' or 't', then $\text{op}(A) = A'$;</p> <p>if <i>transa</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A')$.</p>
<i>transb</i>	<p>CHARACTER*1. Specifies the form of $\text{op}(B)$ used in the matrix multiplication:</p> <p>if <i>transb</i> = 'N' or 'n', then $\text{op}(B) = B$;</p> <p>if <i>transb</i> = 'T' or 't', then $\text{op}(B) = B'$;</p> <p>if <i>transb</i> = 'C' or 'c', then $\text{op}(B) = \text{conjg}(B')$.</p>
<i>m</i>	<p>INTEGER. Specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix <i>C</i>. The value of <i>m</i> must be at least zero.</p>
<i>n</i>	<p>INTEGER. Specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix <i>C</i>. The value of <i>n</i> must be at least zero.</p>
<i>k</i>	<p>INTEGER. Specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. The value of <i>k</i> must be at least zero.</p>
<i>alpha</i>	<p>REAL for <i>sgemm</i> DOUBLE PRECISION for <i>dgemm</i> COMPLEX for <i>cgemm</i>, <i>scgemm</i> DOUBLE COMPLEX for <i>zgemm</i>, <i>dzgemm</i> Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>REAL for <i>sgemm</i>, <i>scgemm</i> DOUBLE PRECISION for <i>dgemm</i>, <i>dzgemm</i> COMPLEX for <i>cgemm</i> DOUBLE COMPLEX for <i>zgemm</i> Array, DIMENSION (<i>lda</i>, <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>transa</i> = 'N' or 'n', and is <i>m</i> otherwise. Before entry with <i>transa</i> = 'N' or 'n', the leading <i>m</i>-by-<i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i>, otherwise the leading <i>k</i>-by-<i>m</i> part of the array <i>a</i> must contain the matrix <i>A</i>.</p>

<i>lda</i>	<p>INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>transa</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, m)$, otherwise <i>lda</i> must be at least $\max(1, k)$.</p>
<i>b</i>	<p>REAL for <i>sgemm</i> DOUBLE PRECISION for <i>dgemm</i> COMPLEX for <i>cgemm</i>, <i>scgemm</i> DOUBLE COMPLEX for <i>zgemm</i>, <i>dzgemm</i> Array, DIMENSION (<i>ldb</i>, <i>kb</i>), where <i>kb</i> is <i>n</i> when <i>transb</i> = 'N' or 'n', and is <i>k</i> otherwise. Before entry with <i>transb</i> = 'N' or 'n', the leading <i>k</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>, otherwise the leading <i>n</i>-by-<i>k</i> part of the array <i>b</i> must contain the matrix <i>B</i>.</p>
<i>ldb</i>	<p>INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program. When <i>transb</i> = 'N' or 'n', then <i>ldb</i> must be at least $\max(1, k)$, otherwise <i>ldb</i> must be at least $\max(1, n)$.</p>
<i>beta</i>	<p>REAL for <i>sgemm</i> DOUBLE PRECISION for <i>dgemm</i> COMPLEX for <i>cgemm</i>, <i>scgemm</i> DOUBLE COMPLEX for <i>zgemm</i>, <i>dzgemm</i> Specifies the scalar <i>beta</i>. When <i>beta</i> is equal to zero, then <i>c</i> need not be set on input.</p>
<i>c</i>	<p>REAL for <i>sgemm</i> DOUBLE PRECISION for <i>dgemm</i> COMPLEX for <i>cgemm</i>, <i>scgemm</i> DOUBLE COMPLEX for <i>zgemm</i>, <i>dzgemm</i> Array, DIMENSION (<i>ldc</i>, <i>n</i>). Before entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i>, except when <i>beta</i> is equal to zero, in which case <i>c</i> need not be set on entry.</p>
<i>ldc</i>	<p>INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program. The value of <i>ldc</i> must be at least $\max(1, m)$.</p>

Output Parameters

c Overwritten by the *m*-by-*n* matrix ($\alpha * \text{op}(A) * \text{op}(B) + \beta * C$).

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gemm` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>ma,ka</i>) where <i>ka</i> = <i>k</i> if <i>transa</i> = 'N', <i>ka</i> = <i>m</i> otherwise, <i>ma</i> = <i>m</i> if <i>transa</i> = 'N', <i>ma</i> = <i>k</i> otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (<i>mb,kb</i>) where <i>kb</i> = <i>n</i> if <i>transb</i> = 'N', <i>kb</i> = <i>k</i> otherwise, <i>mb</i> = <i>k</i> if <i>transb</i> = 'N', <i>mb</i> = <i>n</i> otherwise.
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m,n</i>).
<i>transa</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>transb</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?hemm

Computes a scalar-matrix-matrix product (either one of the matrices is Hermitian) and adds the result to scalar-matrix product.

Syntax

FORTRAN 77:

```
call chemm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc)
call zhemm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call hemm(a, b, c [,side][,uplo] [,alpha][,beta])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?hemm routines perform a matrix-matrix operation using Hermitian matrices. The operation is defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * B * A + \beta * C,$$

where:

alpha and *beta* are scalars,

A is an Hermitian matrix,

B and *C* are *m*-by-*n* matrices.

Input Parameters

side CHARACTER*1. Specifies whether the Hermitian matrix *A* appears on the left or right in the operation as follows:
 if *side* = 'L' or 'l', then $C := \alpha * A * B + \beta * C$;
 if *side* = 'R' or 'r', then $C := \alpha * B * A + \beta * C$.

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is used:</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the Hermitian matrix <i>A</i> is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the Hermitian matrix <i>A</i> is used.</p>
<i>m</i>	<p>INTEGER. Specifies the number of rows of the matrix <i>C</i>. The value of <i>m</i> must be at least zero.</p>
<i>n</i>	<p>INTEGER. Specifies the number of columns of the matrix <i>C</i>. The value of <i>n</i> must be at least zero.</p>
<i>alpha</i>	<p>COMPLEX for chemm DOUBLE COMPLEX for zhemm</p> <p>Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>COMPLEX for chemm DOUBLE COMPLEX for zhemm</p> <p>Array, DIMENSION (<i>lda</i>,<i>ka</i>), where <i>ka</i> is <i>m</i> when <i>side</i> = 'L' or 'l' and is <i>n</i> otherwise. Before entry with <i>side</i> = 'L' or 'l', the <i>m</i>-by-<i>m</i> part of the array <i>a</i> must contain the Hermitian matrix, such that when <i>uplo</i> = 'U' or 'u', the leading <i>m</i>-by-<i>m</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>a</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the leading <i>m</i>-by-<i>m</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the Hermitian matrix, and the strictly upper triangular part of <i>a</i> is not referenced.</p> <p>Before entry with <i>side</i> = 'R' or 'r', the <i>n</i>-by-<i>n</i> part of the array <i>a</i> must contain the Hermitian matrix, such that when <i>uplo</i> = 'U' or 'u', the leading <i>n</i>-by-<i>n</i> upper triangular part of the array <i>a</i> must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of <i>a</i> is not referenced, and when <i>uplo</i> = 'L' or 'l', the leading <i>n</i>-by-<i>n</i> lower triangular part of the array <i>a</i> must contain the lower triangular part of the Hermitian matrix, and the strictly upper triangular part of <i>a</i> is not referenced. The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.</p>

<i>lda</i>	INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub) program. When <i>side</i> = 'L' or 'l' then <i>lda</i> must be at least $\max(1, m)$, otherwise <i>lda</i> must be at least $\max(1, n)$.
<i>b</i>	COMPLEX for chemm DOUBLE COMPLEX for zhemm Array, DIMENSION (<i>ldb</i> , <i>n</i>). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> .
<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program. The value of <i>ldb</i> must be at least $\max(1, m)$.
<i>beta</i>	COMPLEX for chemm DOUBLE COMPLEX for zhemm Specifies the scalar <i>beta</i> . When <i>beta</i> is supplied as zero, then <i>c</i> need not be set on input.
<i>c</i>	COMPLEX for chemm DOUBLE COMPLEX for zhemm Array, DIMENSION (<i>c</i> , <i>n</i>). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> , except when <i>beta</i> is zero, in which case <i>c</i> need not be set on entry.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program. The value of <i>ldc</i> must be at least $\max(1, m)$.

Output Parameters

<i>c</i>	Overwritten by the <i>m</i> -by- <i>n</i> updated matrix.
----------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hemm` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>k</i> , <i>k</i>) where <i>k</i> = <i>m</i> if <i>side</i> = 'L',
----------	--

	$k = n$ otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (m,n) .
<i>c</i>	Holds the matrix <i>C</i> of size (m,n) .
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?herk

Performs a rank-*k* update of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cherk(uplo, trans, n, k, alpha, a, lda, beta, c, ldc)
call zherk(uplo, trans, n, k, alpha, a, lda, beta, c, ldc)
```

Fortran 95:

```
call herk(a, c [,uplo] [, trans] [,alpha][,beta])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?herk routines perform a matrix-matrix operation using Hermitian matrices. The operation is defined as

$$C := \alpha * A * \text{conjg}(A') + \beta * C,$$

or

$$C := \alpha * \text{conjg}(A') * A + \beta * C,$$

where:

alpha and *beta* are real scalars,

C is an *n*-by-*n* Hermitian matrix,

A is an *n*-by-*k* matrix in the first case and a *k*-by-*n* matrix in the second case.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>c</i> is used.</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>c</i> is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>c</i> is used.</p>
<i>trans</i>	<p>CHARACTER*1. Specifies the operation:</p> <p>if <i>trans</i> = 'N' or 'n', then $C := \alpha * A * \text{conjg}(A') + \beta * C$;</p> <p>if <i>trans</i> = 'C' or 'c', then $C := \alpha * \text{conjg}(A') * A + \beta * C$.</p>
<i>n</i>	<p>INTEGER. Specifies the order of the matrix <i>C</i>. The value of <i>n</i> must be at least zero.</p>
<i>k</i>	<p>INTEGER. With <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>A</i>, and with <i>trans</i> = 'C' or 'c', <i>k</i> specifies the number of rows of the matrix <i>A</i>. The value of <i>k</i> must be at least zero.</p>
<i>alpha</i>	<p>REAL for cherk DOUBLE PRECISION for zherk Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>COMPLEX for cherk DOUBLE COMPLEX for zherk Array, DIMENSION (<i>lda</i>, <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i>-by-<i>k</i> part of the array <i>a</i> must contain the matrix <i>a</i>, otherwise the leading <i>k</i>-by-<i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i>.</p>
<i>lda</i>	<p>INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, n)$, otherwise <i>lda</i> must be at least $\max(1, k)$.</p>
<i>beta</i>	<p>REAL for cherk DOUBLE PRECISION for zherk Specifies the scalar <i>beta</i>.</p>
<i>c</i>	<p>COMPLEX for cherk</p>

DOUBLE COMPLEX for zherk

Array, DIMENSION (ldc, n).

Before entry with $uplo = 'U'$ or $'u'$, the leading n -by- n upper triangular part of the array c must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of c is not referenced.

Before entry with $uplo = 'L'$ or $'l'$, the leading n -by- n lower triangular part of the array c must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of c is not referenced.

The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

ldc

INTEGER. Specifies the first dimension of c as declared in the calling (sub)program. The value of ldc must be at least $\max(1, n)$.

Output Parameters

c

With $uplo = 'U'$ or $'u'$, the upper triangular part of the array c is overwritten by the upper triangular part of the updated matrix.

With $uplo = 'L'$ or $'l'$, the lower triangular part of the array c is overwritten by the lower triangular part of the updated matrix.

The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `herk` interface are the following:

a

Holds the matrix A of size (m_a, k_a) where

$k_a = k$ if $transa = 'N'$,

$k_a = n$ otherwise,

$m_a = n$ if $transa = 'N'$,

$m_a = k$ otherwise.

c

Holds the matrix C of size (n, n) .

<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N' or 'C'. The default value is 'N'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?her2k

Performs a rank-2k update of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call cher2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call zher2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call her2k(a, b, c [,uplo][,trans] [,alpha][,beta])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?her2k routines perform a rank-2k matrix-matrix operation using Hermitian matrices. The operation is defined as

$$C := \alpha * A * \text{conjg}(B') + \text{conjg}(\alpha) * B * \text{conjg}(A') + \beta * C,$$

or

$$C := \alpha * \text{conjg}(B') * A + \text{conjg}(\alpha) * \text{conjg}(A') * B + \beta * C,$$

where:

alpha is a scalar and *beta* is a real scalar,

C is an *n*-by-*n* Hermitian matrix,

A and *B* are *n*-by-*k* matrices in the first case and *k*-by-*n* matrices in the second case.

Input Parameters

uplo CHARACTER*1. Specifies whether the upper or lower triangular part of the array *c* is used.

	<p>If <i>uplo</i> = 'U' or 'u', then the upper triangular of the array <i>c</i> is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular of the array <i>c</i> is used.</p>
<i>trans</i>	<p>CHARACTER*1. Specifies the operation:</p> <p>if <i>trans</i> = 'N' or 'n', then $C := \alpha * A * \text{conjg}(B') + \alpha * B * \text{conjg}(A') + \beta * C$;</p> <p>if <i>trans</i> = 'C' or 'c', then $C := \alpha * \text{conjg}(A') * B + \alpha * \text{conjg}(B') * A + \beta * C$.</p>
<i>n</i>	<p>INTEGER. Specifies the order of the matrix <i>c</i>. The value of <i>n</i> must be at least zero.</p>
<i>k</i>	<p>INTEGER. With <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>A</i>, and with <i>trans</i> = 'C' or 'c', <i>k</i> specifies the number of rows of the matrix <i>A</i>. The value of <i>k</i> must be at least equal to zero.</p>
<i>alpha</i>	<p>COMPLEX for cher2k DOUBLE COMPLEX for zher2k Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>COMPLEX for cher2k DOUBLE COMPLEX for zher2k Array, DIMENSION (<i>lda</i>, <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i>-by-<i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i>, otherwise the leading <i>k</i>-by-<i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i>.</p>
<i>lda</i>	<p>INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, n)$, otherwise <i>lda</i> must be at least $\max(1, k)$.</p>
<i>beta</i>	<p>REAL for cher2k DOUBLE PRECISION for zher2k Specifies the scalar <i>beta</i>.</p>
<i>b</i>	<p>COMPLEX for cher2k DOUBLE COMPLEX for zher2k</p>

Array, DIMENSION (ldb , kb), where kb is k when $trans = 'N'$ or $'n'$, and is n otherwise. Before entry with $trans = 'N'$ or $'n'$, the leading n -by- k part of the array b must contain the matrix B , otherwise the leading k -by- n part of the array b must contain the matrix B .

ldb INTEGER. Specifies the first dimension of b as declared in the calling (sub)program. When $trans = 'N'$ or $'n'$, then ldb must be at least $\max(1, n)$, otherwise ldb must be at least $\max(1, k)$.

c COMPLEX for `cher2k`
DOUBLE COMPLEX for `zher2k`
Array, DIMENSION (ldc, n).
Before entry with $uplo = 'U'$ or $'u'$, the leading n -by- n upper triangular part of the array c must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of c is not referenced.
Before entry with $uplo = 'L'$ or $'l'$, the leading n -by- n lower triangular part of the array c must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of c is not referenced.
The imaginary parts of the diagonal elements need not be set, they are assumed to be zero.

ldc INTEGER. Specifies the first dimension of c as declared in the calling (sub)program. The value of ldc must be at least $\max(1, n)$.

Output Parameters

c With $uplo = 'U'$ or $'u'$, the upper triangular part of the array c is overwritten by the upper triangular part of the updated matrix.
With $uplo = 'L'$ or $'l'$, the lower triangular part of the array c is overwritten by the lower triangular part of the updated matrix.
The imaginary parts of the diagonal elements are set to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `her2k` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m_a, k_a) where $k_a = k$ if <i>trans</i> = 'N', $k_a = n$ otherwise, $m_a = n$ if <i>trans</i> = 'N', $m_a = k$ otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (m_b, k_b) where $k_b = k$ if <i>trans</i> = 'N', $k_b = n$ otherwise, $m_b = n$ if <i>trans</i> = 'N', $m_b = k$ otherwise.
<i>c</i>	Holds the matrix <i>C</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N' or 'C'. The default value is 'N'.
<i>alpha</i>	The default value is 1.
<i>beta</i>	The default value is 0.

?symm

Performs a scalar-matrix-matrix product (one matrix operand is symmetric) and adds the result to a scalar-matrix product.

Syntax

FORTRAN 77:

```
call ssymm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc)
call dsymm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc)
call csymm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc)
call zsymm(side, uplo, m, n, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call symm(a, b, c [,side][,uplo] [,alpha][,beta])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?symm` routines perform a matrix-matrix operation using symmetric matrices. The operation is defined as

$$C := \alpha * A * B + \beta * C,$$

or

$$C := \alpha * B * A + \beta * C,$$

where:

alpha and *beta* are scalars,

A is a symmetric matrix,

B and *C* are *m*-by-*n* matrices.

Input Parameters

<i>side</i>	CHARACTER*1. Specifies whether the symmetric matrix <i>A</i> appears on the left or right in the operation: if <i>side</i> = 'L' or 'l', then $C := \alpha * A * B + \beta * C$; if <i>side</i> = 'R' or 'r', then $C := \alpha * B * A + \beta * C$.
<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is used: if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used; if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.
<i>m</i>	INTEGER. Specifies the number of rows of the matrix <i>C</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of the matrix <i>C</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	REAL for <code>ssymm</code> DOUBLE PRECISION for <code>dsymm</code> COMPLEX for <code>csymm</code> DOUBLE COMPLEX for <code>zsymm</code>

Specifies the scalar *alpha*.

a REAL for *ssymm*
DOUBLE PRECISION for *dsymm*
COMPLEX for *csymm*
DOUBLE COMPLEX for *zsymm*
Array, DIMENSION (*lda*, *ka*), where *ka* is *m* when *side* = 'L' or 'l' and is *n* otherwise.
Before entry with *side* = 'L' or 'l', the *m*-by-*m* part of the array *a* must contain the symmetric matrix, such that when *uplo* = 'U' or 'u', the leading *m*-by-*m* upper triangular part of the array *a* must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of *a* is not referenced, and when *uplo* = 'L' or 'l', the leading *m*-by-*m* lower triangular part of the array *a* must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of *a* is not referenced.
Before entry with *side* = 'R' or 'r', the *n*-by-*n* part of the array *a* must contain the symmetric matrix, such that when *uplo* = 'U' or 'u', the leading *n*-by-*n* upper triangular part of the array *a* must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of *a* is not referenced, and when *uplo* = 'L' or 'l', the leading *n*-by-*n* lower triangular part of the array *a* must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of *a* is not referenced.

lda INTEGER. Specifies the first dimension of *a* as declared in the calling (sub)program. When *side* = 'L' or 'l' then *lda* must be at least $\max(1, m)$, otherwise *lda* must be at least $\max(1, n)$.

b REAL for *ssymm*
DOUBLE PRECISION for *dsymm*
COMPLEX for *csymm*
DOUBLE COMPLEX for *zsymm*
Array, DIMENSION (*ldb*, *n*). Before entry, the leading *m*-by-*n* part of the array *b* must contain the matrix *B*.

<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program. The value of <i>ldb</i> must be at least $\max(1, m)$.
<i>beta</i>	REAL for <i>ssymm</i> DOUBLE PRECISION for <i>dsymm</i> COMPLEX for <i>csymm</i> DOUBLE COMPLEX for <i>zsymm</i> Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <i>c</i> need not be set on input.
<i>c</i>	REAL for <i>ssymm</i> DOUBLE PRECISION for <i>dsymm</i> COMPLEX for <i>csymm</i> DOUBLE COMPLEX for <i>zsymm</i> Array, DIMENSION (<i>ldc</i> , <i>n</i>). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> , except when <i>beta</i> is zero, in which case <i>c</i> need not be set on entry.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program. The value of <i>ldc</i> must be at least $\max(1, m)$.

Output Parameters

<i>c</i>	Overwritten by the <i>m</i> -by- <i>n</i> updated matrix.
----------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *symm* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>k</i> , <i>k</i>) where <i>k</i> = <i>m</i> if <i>side</i> = 'L', <i>k</i> = <i>n</i> otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (<i>m</i> , <i>n</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the upper or lower triangular part of the array <i>c</i> is used.</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>c</i> is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>c</i> is used.</p>
<i>trans</i>	<p>CHARACTER*1. Specifies the operation:</p> <p>if <i>trans</i> = 'N' or 'n', then $C := \alpha * A * A' + \beta * C$;</p> <p>if <i>trans</i> = 'T' or 't', then $C := \alpha * A' * A + \beta * C$;</p> <p>if <i>trans</i> = 'C' or 'c', then $C := \alpha * A' * A + \beta * C$.</p>
<i>n</i>	<p>INTEGER. Specifies the order of the matrix <i>c</i>. The value of <i>n</i> must be at least zero.</p>
<i>k</i>	<p>INTEGER. On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>a</i>, and on entry with <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>k</i> specifies the number of rows of the matrix <i>a</i>.</p> <p>The value of <i>k</i> must be at least zero.</p>
<i>alpha</i>	<p>REAL for ssyrk DOUBLE PRECISION for dsyrk COMPLEX for csyrk DOUBLE COMPLEX for zsyrk</p> <p>Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>REAL for ssyrk DOUBLE PRECISION for dsyrk COMPLEX for csyrk DOUBLE COMPLEX for zsyrk</p> <p>Array, DIMENSION (<i>lda</i>, <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>trans</i> = 'N' or 'n', and is <i>n</i> otherwise. Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i>-by-<i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i>, otherwise the leading <i>k</i>-by-<i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i>.</p>
<i>lda</i>	<p>INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>trans</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, n)$, otherwise <i>lda</i> must be at least $\max(1, k)$.</p>

<i>beta</i>	REAL for <i>ssyrk</i> DOUBLE PRECISION for <i>dsyrk</i> COMPLEX for <i>csyrk</i> DOUBLE COMPLEX for <i>zsyrk</i> Specifies the scalar <i>beta</i> .
<i>c</i>	REAL for <i>ssyrk</i> DOUBLE PRECISION for <i>dsyrk</i> COMPLEX for <i>csyrk</i> DOUBLE COMPLEX for <i>zsyrk</i> Array, DIMENSION (<i>ldc</i> , <i>n</i>). Before entry with <i>uplo</i> = 'U' or 'u', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>c</i> must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of <i>c</i> is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>c</i> must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of <i>c</i> is not referenced.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program. The value of <i>ldc</i> must be at least $\max(1, n)$.

Output Parameters

<i>c</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array <i>c</i> is overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array <i>c</i> is overwritten by the lower triangular part of the updated matrix.
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *syrk* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>ma</i> , <i>ka</i>) where <i>ka</i> = <i>k</i> if <i>transa</i> = 'N',
----------	---

	$ka = n$ otherwise, $ma = n$ if $transa = 'N'$, $ma = k$ otherwise.
c	Holds the matrix C of size (n,n) .
$uplo$	Must be 'U' or 'L'. The default value is 'U'.
$trans$	Must be 'N', 'C', or 'T'. The default value is 'N'.
$alpha$	The default value is 1.
$beta$	The default value is 0.

?syr2k

Performs a rank-2k update of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyr2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call dsyr2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call csyr2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call zsyr2k(uplo, trans, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call syr2k(a, b, c [,uplo][,trans] [,alpha][,beta])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?syr2k` routines perform a rank-2k matrix-matrix operation using symmetric matrices. The operation is defined as

$$C := \alpha * A * B' + \alpha * B * A' + \beta * C,$$

or

$$C := \alpha * a' * B + \alpha * B' * A + \beta * C,$$

where:

α and β are scalars,
 C is an n -by- n symmetric matrix,
 A and B are n -by- k matrices in the first case, and k -by- n matrices in the second case.

Input Parameters

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or lower triangular part of the array c is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array c is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array c is used.
<i>trans</i>	CHARACTER*1. Specifies the operation: if <i>trans</i> = 'N' or 'n', then $C := \alpha * A * B' + \alpha * B * A' + \beta * C$; if <i>trans</i> = 'T' or 't', then $C := \alpha * A' * B + \alpha * B' * A + \beta * C$; if <i>trans</i> = 'C' or 'c', then $C := \alpha * A' * B + \alpha * B' * A + \beta * C$.
<i>n</i>	INTEGER. Specifies the order of the matrix c . The value of n must be at least zero.
<i>k</i>	INTEGER. On entry with <i>trans</i> = 'N' or 'n', k specifies the number of columns of the matrices A and B , and on entry with <i>trans</i> = 'T' or 't' or 'C' or 'c', k specifies the number of rows of the matrices A and B . The value of k must be at least zero.
<i>alpha</i>	REAL for <i>ssyr2k</i> DOUBLE PRECISION for <i>dsyr2k</i> COMPLEX for <i>csyr2k</i> DOUBLE COMPLEX for <i>zsyr2k</i> Specifies the scalar α .
<i>a</i>	REAL for <i>ssyr2k</i> DOUBLE PRECISION for <i>dsyr2k</i> COMPLEX for <i>csyr2k</i> DOUBLE COMPLEX for <i>zsyr2k</i>

	<p>Array, DIMENSION (lda, ka), where ka is k when $trans = 'N'$ or $'n'$, and is n otherwise. Before entry with $trans = 'N'$ or $'n'$, the leading n-by-k part of the array a must contain the matrix A, otherwise the leading k-by-n part of the array a must contain the matrix A.</p>
<i>lda</i>	<p>INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. When $trans = 'N'$ or $'n'$, then lda must be at least $\max(1, n)$, otherwise lda must be at least $\max(1, k)$.</p>
<i>b</i>	<p>REAL for <code>ssyr2k</code> DOUBLE PRECISION for <code>dsyr2k</code> COMPLEX for <code>csyr2k</code> DOUBLE COMPLEX for <code>zsyr2k</code></p> <p>Array, DIMENSION (ldb, kb) where kb is k when $trans = 'N'$ or $'n'$ and is n otherwise. Before entry with $trans = 'N'$ or $'n'$, the leading n-by-k part of the array b must contain the matrix B, otherwise the leading k-by-n part of the array b must contain the matrix B.</p>
<i>ldb</i>	<p>INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. When $trans = 'N'$ or $'n'$, then ldb must be at least $\max(1, n)$, otherwise ldb must be at least $\max(1, k)$.</p>
<i>beta</i>	<p>REAL for <code>ssyr2k</code> DOUBLE PRECISION for <code>dsyr2k</code> COMPLEX for <code>csyr2k</code> DOUBLE COMPLEX for <code>zsyr2k</code></p> <p>Specifies the scalar β.</p>
<i>c</i>	<p>REAL for <code>ssyr2k</code> DOUBLE PRECISION for <code>dsyr2k</code> COMPLEX for <code>csyr2k</code> DOUBLE COMPLEX for <code>zsyr2k</code></p> <p>Array, DIMENSION (ldc, n). Before entry with $uplo = 'U'$ or $'u'$, the leading n-by-n upper triangular part of the array c must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of c is not referenced.</p>

Before entry with *uplo* = 'L' or 'l', the leading *n*-by-*n* lower triangular part of the array *c* must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of *c* is not referenced.

ldc INTEGER. Specifies the first dimension of *c* as declared in the calling (sub)program. The value of *ldc* must be at least $\max(1, n)$.

Output Parameters

c With *uplo* = 'U' or 'u', the upper triangular part of the array *c* is overwritten by the upper triangular part of the updated matrix.
 With *uplo* = 'L' or 'l', the lower triangular part of the array *c* is overwritten by the lower triangular part of the updated matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *syr2k* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>ma,ka</i>) where $ka = k$ if <i>trans</i> = 'N', $ka = n$ otherwise, $ma = n$ if <i>trans</i> = 'N', $ma = k$ otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (<i>mb,kb</i>) where $kb = k$ if <i>trans</i> = 'N', $kb = n$ otherwise, $mb = n$ if <i>trans</i> = 'N', $mb = k$ otherwise.
<i>c</i>	Holds the matrix <i>C</i> of size (<i>n,n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>alpha</i>	The default value is 1.

beta

The default value is 0.

?trmm

Computes a scalar-matrix-matrix product (one matrix operand is triangular).

Syntax

FORTRAN 77:

```
call strmm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
call dtrmm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
call ctrmm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
call ztrmm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
```

Fortran 95:

```
call trmm(a, b [,side] [, uplo] [,transa][,diag] [,alpha])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?trmm` routines perform a matrix-matrix operation using triangular matrices. The operation is defined as

$$B := \alpha * \text{op}(A) * B$$

or

$$B := \alpha * B * \text{op}(A)$$

where:

alpha is a scalar,

B is an *m*-by-*n* matrix,

A is a unit, or non-unit, upper or lower triangular matrix

`op(A)` is one of `op(A) = A`, or `op(A) = A'`, or `op(A) = conjg(A')`.

Input Parameters

<i>side</i>	<p>CHARACTER*1. Specifies whether $\text{op}(A)$ appears on the left or right of B in the operation:</p> <p>if <i>side</i> = 'L' or 'l', then $B := \alpha * \text{op}(A) * B$;</p> <p>if <i>side</i> = 'R' or 'r', then $B := \alpha * B * \text{op}(A)$.</p>
<i>uplo</i>	<p>CHARACTER*1. Specifies whether the matrix A is upper or lower triangular:</p> <p>if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular;</p> <p>if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.</p>
<i>transa</i>	<p>CHARACTER*1. Specifies the form of $\text{op}(A)$ used in the matrix multiplication:</p> <p>if <i>transa</i> = 'N' or 'n', then $\text{op}(A) = A$;</p> <p>if <i>transa</i> = 'T' or 't', then $\text{op}(A) = A'$;</p> <p>if <i>transa</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A)$.</p>
<i>diag</i>	<p>CHARACTER*1. Specifies whether the matrix A is unit triangular:</p> <p>if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular;</p> <p>if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.</p>
<i>m</i>	<p>INTEGER. Specifies the number of rows of B. The value of m must be at least zero.</p>
<i>n</i>	<p>INTEGER. Specifies the number of columns of B. The value of n must be at least zero.</p>
<i>alpha</i>	<p>REAL for <i>strmm</i> DOUBLE PRECISION for <i>dtrmm</i> COMPLEX for <i>ctrmm</i> DOUBLE COMPLEX for <i>ztrmm</i></p> <p>Specifies the scalar <i>alpha</i>. When <i>alpha</i> is zero, then a is not referenced and b need not be set before entry.</p>
<i>a</i>	<p>REAL for <i>strmm</i> DOUBLE PRECISION for <i>dtrmm</i> COMPLEX for <i>ctrmm</i> DOUBLE COMPLEX for <i>ztrmm</i></p>

Array, DIMENSION (lda, k), where k is m when $side = 'L'$ or $'l'$ and is n when $side = 'R'$ or $'r'$. Before entry with $uplo = 'U'$ or $'u'$, the leading k by k upper triangular part of the array a must contain the upper triangular matrix and the strictly lower triangular part of a is not referenced. Before entry with $uplo = 'L'$ or $'l'$, the leading k by k lower triangular part of the array a must contain the lower triangular matrix and the strictly upper triangular part of a is not referenced.

When $diag = 'U'$ or $'u'$, the diagonal elements of a are not referenced either, but are assumed to be unity.

lda	INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. When $side = 'L'$ or $'l'$, then lda must be at least $\max(1, m)$, when $side = 'R'$ or $'r'$, then lda must be at least $\max(1, n)$.
b	REAL for <code>strmm</code> DOUBLE PRECISION for <code>dtrmm</code> COMPLEX for <code>ctrmm</code> DOUBLE COMPLEX for <code>ztrmm</code> Array, DIMENSION (ldb, n). Before entry, the leading m -by- n part of the array b must contain the matrix B .
ldb	INTEGER. Specifies the first dimension of b as declared in the calling (sub)program. The value of ldb must be at least $\max(1, m)$.

Output Parameters

b Overwritten by the transformed matrix.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trmm` interface are the following:

a Holds the matrix A of size (k, k) where
 $k = m$ if $side = 'L'$,

	$k = n$ otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (m,n) .
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>transa</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.
<i>alpha</i>	The default value is 1.

?trsm

Solves a matrix equation (one matrix operand is triangular).

Syntax

FORTRAN 77:

```
call strsm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
call dtrsm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
call ctrsm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
call ztrsm(side, uplo, transa, diag, m, n, alpha, a, lda, b, ldb)
```

Fortran 95:

```
call trsm(a, b [,side] [, uplo] [,transa][,diag] [,alpha])
```

Description

This routine is declared in `mk1_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mk1_blas.h` for C interface.

The ?trsm routines solve one of the following matrix equations:

$$\text{op}(A)*X = \text{alpha}*B,$$

or

$$X*\text{op}(A) = \text{alpha}*B,$$

where:

alpha is a scalar,

X and B are m -by- n matrices,

A is a unit, or non-unit, upper or lower triangular matrix

$\text{op}(A)$ is one of $\text{op}(A) = A$, or $\text{op}(A) = A'$, or $\text{op}(A) = \text{conjg}(A')$.

The matrix B is overwritten by the solution matrix X .

Input Parameters

<i>side</i>	CHARACTER*1. Specifies whether $\text{op}(A)$ appears on the left or right of X in the equation: if <i>side</i> = 'L' or 'l', then $\text{op}(A)*X = \text{alpha}*B$; if <i>side</i> = 'R' or 'r', then $X*\text{op}(A) = \text{alpha}*B$.
<i>uplo</i>	CHARACTER*1. Specifies whether the matrix A is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>transa</i>	CHARACTER*1. Specifies the form of $\text{op}(A)$ used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then $\text{op}(A) = A$; if <i>transa</i> = 'T' or 't', then $\text{op}(A) = A'$; if <i>transa</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A')$.
<i>diag</i>	CHARACTER*1. Specifies whether the matrix A is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>m</i>	INTEGER. Specifies the number of rows of B . The value of m must be at least zero.
<i>n</i>	INTEGER. Specifies the number of columns of B . The value of n must be at least zero.
<i>alpha</i>	REAL for <i>strsm</i> DOUBLE PRECISION for <i>dtrsm</i> COMPLEX for <i>ctrsm</i> DOUBLE COMPLEX for <i>ztrsm</i> Specifies the scalar <i>alpha</i> . When <i>alpha</i> is zero, then a is not referenced and b need not be set before entry.
<i>a</i>	REAL for <i>strsm</i> DOUBLE PRECISION for <i>dtrsm</i>

COMPLEX for `ctrsm`
 DOUBLE COMPLEX for `ztrsm`
 Array, DIMENSION (lda, k), where k is m when $side = 'L'$ or $'l'$ and is n when $side = 'R'$ or $'r'$. Before entry with $uplo = 'U'$ or $'u'$, the leading k by k upper triangular part of the array a must contain the upper triangular matrix and the strictly lower triangular part of a is not referenced. Before entry with $uplo = 'L'$ or $'l'$, the leading k by k lower triangular part of the array a must contain the lower triangular matrix and the strictly upper triangular part of a is not referenced.
 When $diag = 'U'$ or $'u'$, the diagonal elements of a are not referenced either, but are assumed to be unity.

lda INTEGER. Specifies the first dimension of a as declared in the calling (sub)program. When $side = 'L'$ or $'l'$, then lda must be at least $\max(1, m)$, when $side = 'R'$ or $'r'$, then lda must be at least $\max(1, n)$.

b REAL for `strsm`
 DOUBLE PRECISION for `dtrsm`
 COMPLEX for `ctrsm`
 DOUBLE COMPLEX for `ztrsm`
 Array, DIMENSION (ldb, n). Before entry, the leading m -by- n part of the array b must contain the right-hand side matrix B .

ldb INTEGER. Specifies the first dimension of b as declared in the calling (sub)program. The value of ldb must be at least $\max(1, +m)$.

Output Parameters

b Overwritten by the solution matrix x .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trsm` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (k,k) where $k = m$ if <i>side</i> = 'L', $k = n$ otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (m,n) .
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>transa</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.
<i>alpha</i>	The default value is 1.

Sparse BLAS Level 1 Routines

This section describes Sparse BLAS Level 1, an extension of BLAS Level 1 included in the Intel® Math Kernel Library beginning with the Intel MKL release 2.1. Sparse BLAS Level 1 is a group of routines and functions that perform a number of common vector operations on sparse vectors stored in compressed form.

Sparse vectors are those in which the majority of elements are zeros. Sparse BLAS routines and functions are specially implemented to take advantage of vector sparsity. This allows you to achieve large savings in computer time and memory. If *nz* is the number of non-zero vector elements, the computer time taken by Sparse BLAS operations will be $O(nz)$.

Vector Arguments

Compressed sparse vectors. Let *a* be a vector stored in an array, and assume that the only non-zero elements of *a* are the following:

$a(k_1), a(k_2), a(k_3) \dots a(k_{nz}),$

where *nz* is the total number of non-zero elements in *a*.

In Sparse BLAS, this vector can be represented in compressed form by two FORTRAN arrays, *x* (values) and *indx* (indices). Each array has *nz* elements:

$x(1)=a(k_1), x(2)=a(k_2), \dots x(nz)= a(k_{nz}),$

$indx(1)=k_1, indx(2)=k_2, \dots indx(nz)= k_{nz}.$

Thus, a sparse vector is fully determined by the triple $(nz, x, indx)$. If you pass a negative or zero value of *nz* to Sparse BLAS, the subroutines do not modify any arrays or variables.

Full-storage vectors. Sparse BLAS routines can also use a vector argument fully stored in a single FORTRAN array (a full-storage vector). If y is a full-storage vector, its elements must be stored contiguously: the first element in $y(1)$, the second in $y(2)$, and so on. This corresponds to an increment $incy = 1$ in BLAS Level 1. No increment value for full-storage vectors is passed as an argument to Sparse BLAS routines or functions.

Naming Conventions

Similar to BLAS, the names of Sparse BLAS subprograms have prefixes that determine the data type involved: s and d for single- and double-precision real; c and z for single- and double-precision complex respectively.

If a Sparse BLAS routine is an extension of a “dense” one, the subprogram name is formed by appending the suffix i (standing for *indexed*) to the name of the corresponding “dense” subprogram. For example, the Sparse BLAS routine `saxpyi` corresponds to the BLAS routine `saxpy`, and the Sparse BLAS function `cdotci` corresponds to the BLAS function `cdotc`.

Routines and Data Types

Routines and data types supported in the Intel MKL implementation of Sparse BLAS are listed in Table 2-4 .

Table 2-4 Sparse BLAS Routines and Their Data Types

Routine/Function	Data Types	Description
?axpyi	s, d, c, z	Scalar-vector product plus vector (routines)
?doti	s, d	Dot product (functions)
?dotci	c, z	Complex dot product conjugated (functions)
?dotui	c, z	Complex dot product unconjugated (functions)
?gthr	s, d, c, z	Gathering a full-storage sparse vector into compressed form $nz, x, indx$ (routines)
?gthrz	s, d, c, z	Gathering a full-storage sparse vector into compressed form and assigning zeros to gathered elements in the full-storage vector (routines)
?roti	s, d	Givens rotation (routines)

Routine/Function	Data Types	Description
<code>?sctr</code>	s, d, c, z	Scattering a vector from compressed form to full-storage form (routines)

BLAS Level 1 Routines That Can Work With Sparse Vectors

The following BLAS Level 1 routines will give correct results when you pass to them a compressed-form array x (with the increment $incx=1$):

<code>?asum</code>	sum of absolute values of vector elements
<code>?copy</code>	copying a vector
<code>?nrm2</code>	Euclidean norm of a vector
<code>?scal</code>	scaling a vector
<code>i?amax</code>	index of the element with the largest absolute value for real flavors, or the largest sum $ \operatorname{Re}(x(i)) + \operatorname{Im}(x(i)) $ for complex flavors.
<code>i?amin</code>	index of the element with the smallest absolute value for real flavors, or the smallest sum $ \operatorname{Re}(x(i)) + \operatorname{Im}(x(i)) $ for complex flavors.

The result i returned by `i?amax` and `i?amin` should be interpreted as index in the compressed-form array, so that the largest (smallest) value is $x(i)$; the corresponding index in full-storage array is $indx(i)$.

You can also call `?roti` to compute the parameters of Givens rotation and then pass these parameters to the Sparse BLAS routines `?roti`.

`?axpyi`

Adds a scalar multiple of compressed sparse vector to a full-storage vector.

Syntax

FORTRAN 77:

```
call saxpyi(nz, a, x, indx, y)
call daxpyi(nz, a, x, indx, y)
call caxpyi(nz, a, x, indx, y)
call zaxpyi(nz, a, x, indx, y)
```

Fortran 95:

```
call axpyi(x, indx, y [, a])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?axpyi` routines perform a vector-vector operation defined as

$$y := a*x + y$$

where:

a is a scalar,

x is a sparse vector stored in compressed form,

y is a vector in full storage form.

The `?axpyi` routines reference or modify only the elements of *y* whose indices are listed in the array *indx*.

The values in *indx* must be distinct.

Input Parameters

<i>nz</i>	INTEGER. The number of elements in <i>x</i> and <i>indx</i> .
<i>a</i>	REAL for <code>saxpyi</code> DOUBLE PRECISION for <code>daxpyi</code> COMPLEX for <code>caxpyi</code> DOUBLE COMPLEX for <code>zaxpyi</code> Specifies the scalar <i>a</i> .
<i>x</i>	REAL for <code>saxpyi</code> DOUBLE PRECISION for <code>daxpyi</code> COMPLEX for <code>caxpyi</code> DOUBLE COMPLEX for <code>zaxpyi</code> Array, DIMENSION at least <i>nz</i> .
<i>indx</i>	INTEGER. Specifies the indices for the elements of <i>x</i> . Array, DIMENSION at least <i>nz</i> .
<i>y</i>	REAL for <code>saxpyi</code> DOUBLE PRECISION for <code>daxpyi</code> COMPLEX for <code>caxpyi</code>

DOUBLE COMPLEX for `zaxpyi`
Array, DIMENSION at least `max(indx(i))`.

Output Parameters

`y` Contains the updated vector `y`.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `axpyi` interface are the following:

<code>x</code>	Holds the vector with the number of elements <code>nz</code> .
<code>indx</code>	Holds the vector with the number of elements <code>nz</code> .
<code>y</code>	Holds the vector with the number of elements <code>nz</code> .
<code>a</code>	The default value is 1.

?doti

Computes the dot product of a compressed sparse real vector by a full-storage real vector.

Syntax

FORTRAN 77:

```
res = sdoti(nz, x, indx, y )
```

```
res = ddoti(nz, x, indx, y )
```

Fortran 95:

```
res = doti(x, indx, y)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?doti` routines return the dot product of `x` and `y` defined as
$$res = x(1)*y(indx(1)) + x(2)*y(indx(2)) + \dots + x(nz)*y(indx(nz))$$

where the triple $(nz, x, indx)$ defines a sparse real vector stored in compressed form, and y is a real vector in full storage form. The functions reference only the elements of y whose indices are listed in the array $indx$. The values in $indx$ must be distinct.

Input Parameters

nz	INTEGER. The number of elements in x and $indx$.
x	REAL for <code>sdoti</code> DOUBLE PRECISION for <code>ddoti</code> Array, DIMENSION at least nz .
$indx$	INTEGER. Specifies the indices for the elements of x . Array, DIMENSION at least nz .
y	REAL for <code>sdoti</code> DOUBLE PRECISION for <code>ddoti</code> Array, DIMENSION at least $\max(indx(i))$.

Output Parameters

res	REAL for <code>sdoti</code> DOUBLE PRECISION for <code>ddoti</code> Contains the dot product of x and y , if nz is positive. Otherwise, res contains 0.
-------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `doti` interface are the following:

x	Holds the vector with the number of elements nz .
$indx$	Holds the vector with the number of elements nz .
y	Holds the vector with the number of elements nz .

?dotci

Computes the conjugated dot product of a compressed sparse complex vector with a full-storage complex vector.

Syntax

FORTRAN 77:

```
res = cdotci(nz, x, indx, y )
```

```
res = zdotci(nz, x, indx, y )
```

Fortran 95:

```
res = dotci(x, indx, y)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The ?dotci routines return the dot product of x and y defined as

$$\text{conjg}(x(1))*y(\text{indx}(1)) + \dots + \text{conjg}(x(\text{nz}))*y(\text{indx}(\text{nz}))$$

where the triple (nz, x, indx) defines a sparse complex vector stored in compressed form, and y is a real vector in full storage form. The functions reference only the elements of y whose indices are listed in the array indx . The values in indx must be distinct.

Input Parameters

nz	INTEGER. The number of elements in x and indx .
x	COMPLEX for <code>cdotci</code> DOUBLE COMPLEX for <code>zdotci</code> Array, DIMENSION at least nz .
indx	INTEGER. Specifies the indices for the elements of x . Array, DIMENSION at least nz .
y	COMPLEX for <code>cdotci</code> DOUBLE COMPLEX for <code>zdotci</code> Array, DIMENSION at least $\max(\text{indx}(i))$.

Output Parameters

<i>res</i>	COMPLEX for <code>cdotci</code> DOUBLE COMPLEX for <code>zdotci</code> Contains the conjugated dot product of <i>x</i> and <i>y</i> , if <i>nz</i> is positive. Otherwise, <i>res</i> contains 0.
------------	---

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dotci` interface are the following:

<i>x</i>	Holds the vector with the number of elements (<i>nz</i>).
<i>indx</i>	Holds the vector with the number of elements (<i>nz</i>).
<i>y</i>	Holds the vector with the number of elements (<i>nz</i>).

?dotui

Computes the dot product of a compressed sparse complex vector by a full-storage complex vector.

Syntax

FORTRAN 77:

```
res = cdotui(nz, x, indx, y )
```

```
res = zdotui(nz, x, indx, y )
```

Fortran 95:

```
res = dotui(x, indx, y)
```

Description

This routine is declared in `mk1_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mk1_blas.h` for C interface.

The `?dotui` routines return the dot product of *x* and *y* defined as

$$res = x(1)*y(indx(1)) + x(2)*y(indx(2)) + \dots + x(nz)*y(indx(nz))$$

where the triple $(nz, x, indx)$ defines a sparse complex vector stored in compressed form, and y is a real vector in full storage form. The functions reference only the elements of y whose indices are listed in the array $indx$. The values in $indx$ must be distinct.

Input Parameters

<i>nz</i>	INTEGER. The number of elements in x and $indx$.
x	COMPLEX for <code>cdotui</code> DOUBLE COMPLEX for <code>zdotui</code> Array, DIMENSION at least nz .
<i>indx</i>	INTEGER. Specifies the indices for the elements of x . Array, DIMENSION at least nz .
y	COMPLEX for <code>cdotui</code> DOUBLE COMPLEX for <code>zdotui</code> Array, DIMENSION at least $\max(indx(i))$.

Output Parameters

<i>res</i>	COMPLEX for <code>cdotui</code> DOUBLE COMPLEX for <code>zdotui</code> Contains the dot product of x and y , if nz is positive. Otherwise, <i>res</i> contains 0.
------------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `dotui` interface are the following:

x	Holds the vector with the number of elements nz .
<i>indx</i>	Holds the vector with the number of elements nz .
y	Holds the vector with the number of elements nz .

?gthr

Gathers a full-storage sparse vector's elements into compressed form.

Syntax

FORTRAN 77:

```
call sgthr(nz, y, x, indx )
call dgthr(nz, y, x, indx )
call cgthr(nz, y, x, indx )
call zgthr(nz, y, x, indx )
```

Fortran 95:

```
res = gthr(x, indx, y)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?gthr` routines gather the specified elements of a full-storage sparse vector y into compressed form($nz, x, indx$). The routines reference only the elements of y whose indices are listed in the array $indx$:

$x(i) = y(indx(i))$, for $i=1,2,\dots +nz$.

Input Parameters

nz	INTEGER. The number of elements of y to be gathered.
$indx$	INTEGER. Specifies indices of elements to be gathered. Array, DIMENSION at least nz .
y	REAL for <code>sgthr</code> DOUBLE PRECISION for <code>dgthr</code> COMPLEX for <code>cgthr</code> DOUBLE COMPLEX for <code>zgthr</code> Array, DIMENSION at least $\max(indx(i))$.

Output Parameters

x REAL for `sgthr`
 DOUBLE PRECISION for `dgthr`
 COMPLEX for `cgthr`
 DOUBLE COMPLEX for `zgthr`
 Array, DIMENSION at least *nz*.
 Contains the vector converted to the compressed form.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gthr` interface are the following:

x Holds the vector with the number of elements *nz*.
indx Holds the vector with the number of elements *nz*.
y Holds the vector with the number of elements *nz*.

?gthrz

Gathers a sparse vector's elements into compressed form, replacing them by zeros.

Syntax

FORTRAN 77:

```
call sgthrz(nz, y, x, indx )
call dgthrz(nz, y, x, indx )
call cgthrz(nz, y, x, indx )
call zgthrz(nz, y, x, indx )
```

Fortran 95:

```
res = gthrz(x, indx, y)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?gthrz` routines gather the elements with indices specified by the array `indx` from a full-storage vector `y` into compressed form $(nz, x, indx)$ and overwrite the gathered elements of `y` by zeros. Other elements of `y` are not referenced or modified (see also `?gthr`).

Input Parameters

<code>nz</code>	INTEGER. The number of elements of <code>y</code> to be gathered.
<code>indx</code>	INTEGER. Specifies indices of elements to be gathered. Array, DIMENSION at least <code>nz</code> .
<code>y</code>	REAL for <code>sgthrz</code> DOUBLE PRECISION for <code>dgthrz</code> COMPLEX for <code>cgthrz</code> DOUBLE COMPLEX for <code>zgthrz</code> Array, DIMENSION at least $\max(indx(i))$.

Output Parameters

<code>x</code>	REAL for <code>sgthrz</code> DOUBLE PRECISION for <code>dgthrz</code> COMPLEX for <code>cgthrz</code> DOUBLE COMPLEX for <code>zgthrz</code> Array, DIMENSION at least <code>nz</code> . Contains the vector converted to the compressed form.
<code>y</code>	The updated vector <code>y</code> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gthrz` interface are the following:

<code>x</code>	Holds the vector with the number of elements <code>nz</code> .
<code>indx</code>	Holds the vector with the number of elements <code>nz</code> .
<code>y</code>	Holds the vector with the number of elements <code>nz</code> .

?roti

Applies Givens rotation to sparse vectors one of which is in compressed form.

Syntax

FORTRAN 77:

```
call sroti(nz, x, indx, y, c, s)
call droti(nz, x, indx, y, c, s)
```

Fortran 95:

```
call roti(x, indx, y, c, s)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?roti` routines apply the Givens rotation to elements of two real vectors, x (in compressed form $nz, x, indx$) and y (in full storage form):

$$x(i) = c*x(i) + s*y(indx(i))$$

$$y(indx(i)) = c*y(indx(i)) - s*x(i)$$

The routines reference only the elements of y whose indices are listed in the array $indx$. The values in $indx$ must be distinct.

Input Parameters

nz	INTEGER. The number of elements in x and $indx$.
x	REAL for <code>sroti</code> DOUBLE PRECISION for <code>droti</code> Array, DIMENSION at least nz .
$indx$	INTEGER. Specifies the indices for the elements of x . Array, DIMENSION at least nz .
y	REAL for <code>sroti</code> DOUBLE PRECISION for <code>droti</code> Array, DIMENSION at least $\max(indx(i))$.
c	A scalar: REAL for <code>sroti</code>

s DOUBLE PRECISION for *droti*.
A scalar: REAL for *sroti*
DOUBLE PRECISION for *droti*.

Output Parameters

x and *y* The updated arrays.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *roti* interface are the following:

x Holds the vector with the number of elements *nz*.
indx Holds the vector with the number of elements *nz*.
y Holds the vector with the number of elements *nz*.

?sctr

Converts compressed sparse vectors into full storage form.

Syntax

FORTRAN 77:

```
call ssctr(nz, x, indx, y )  
call dsctr(nz, x, indx, y )  
call csctr(nz, x, indx, y )  
call zsctr(nz, x, indx, y )
```

Fortran 95:

```
call sctr(x, indx, y)
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?sctr` routines scatter the elements of the compressed sparse vector ($nz, x, indx$) to a full-storage vector y . The routines modify only the elements of y whose indices are listed in the array $indx$:

$$y(indx(i)) = x(i), \text{ for } i=1,2,\dots, +nz.$$

Input Parameters

nz	INTEGER. The number of elements of x to be scattered.
$indx$	INTEGER. Specifies indices of elements to be scattered. Array, DIMENSION at least nz .
x	REAL for <code>ssctr</code> DOUBLE PRECISION for <code>dsctr</code> COMPLEX for <code>csctr</code> DOUBLE COMPLEX for <code>zsctr</code> Array, DIMENSION at least nz . Contains the vector to be converted to full-storage form.

Output Parameters

y	REAL for <code>ssctr</code> DOUBLE PRECISION for <code>dsctr</code> COMPLEX for <code>csctr</code> DOUBLE COMPLEX for <code>zsctr</code> Array, DIMENSION at least $\max(indx(i))$. Contains the vector y with updated elements.
-----	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sctr` interface are the following:

x	Holds the vector with the number of elements nz .
$indx$	Holds the vector with the number of elements nz .
y	Holds the vector with the number of elements nz .

Sparse BLAS Level 2 and Level 3 Routines

This section describes Sparse BLAS Level 2 and Level 3 routines included in the Intel® Math Kernel Library (Intel® MKL) . Sparse BLAS Level 2 is a group of routines and functions that perform operations between a sparse matrix and dense vectors. Sparse BLAS Level 3 is a group of routines and functions that perform operations between a sparse matrix and dense matrices.

The terms and concepts required to understand the use of the Intel MKL Sparse BLAS Level 2 and Level 3 routines are discussed in the [Linear Solvers Basics](#) appendix.

This Sparse BLAS routines can be useful to implement iterative methods for solving large sparse systems of equations or eigenvalue problems. For example, these routines can be considered as building blocks for “[Iterative Sparse Solvers based on Reverse Communication Interface \(RCI ISS\)](#)” described in the Chapter 8 of the manual.

Intel MKL provides Sparse BLAS Level 2 and Level 3 routines with typical (or conventional) interface similar to the interface used in the NIST* Sparse BLAS library [[Rem05](#)].

Some software packages and libraries (the [PARDISO* Solver](#) used in Intel MKL, *Sparskit 2* [[Saad94](#)], the Compaq* Extended Math Library (CXML)[[CXML01](#)]) use different (early) variation of the compressed sparse row (CSR) format and support only Level 2 operations with simplified interfaces. Intel MKL provides an additional set of Sparse BLAS Level 2 routines with similar simplified interfaces. Each of these routines operates only on a matrix of the fixed type.

The routines described in this section support both one-based indexing and zero-based indexing of the input data (see details in the section [One-based and Zero-based Indexing](#)).

Naming Conventions in Sparse BLAS Level 2 and Level 3

Each Sparse BLAS Level 2 and Level 3 routine has a six- or eight-character base name preceded by the prefix `mkl_` or `mkl_cspblas_` .

The routines with typical (conventional) interface have six-character base names in accordance with the template:

```
mkl_<character> <data> <operation>( )
```

The routines with simplified interfaces have eight-character base names in accordance with the templates:

```
mkl_<character> <data> <mtype> <operation>( )
```

for routines with one-based indexing; and

```
mkl_cspblas_<character> <data> <mtype> <operation>( )
```

for routines with zero-based indexing.

The `<character>` field indicates the data type:

s	real, single precision
c	complex, single precision
d	real, double precision
z	complex, double precision

The `<data>` field indicates the sparse matrix storage format (see section [Sparse Matrix Storage Formats](#)):

coo	coordinate format
csr	compressed sparse row format and its variations
csc	compressed sparse column format and its variations
dia	diagonal format
sky	skyline storage format
bsr	block sparse row format and its variations

The `<operation>` field indicates the type of operation:

mv	matrix-vector product (Level 2)
mm	matrix-matrix product (Level 3)
sv	solving a single triangular system (Level 2)
sm	solving triangular systems with multiple right-hand sides (Level 3)

The field `<mtype>` indicates the matrix type:

ge	sparse representation of a general matrix
sy	sparse representation of the upper or lower triangle of a symmetric matrix
tr	sparse representation of a triangular matrix

Sparse Matrix Storage Formats

The current version of Intel MKL Sparse BLAS Level 2 and Level 3 routines support the following point entry [[Duff86](#)] storage formats for sparse matrices:

- *compressed sparse row* format (CSR) and its variations;
- *compressed sparse column* format (CSC);
- *coordinate* format;
- *diagonal* format;
- *skyline* storage format;

and one block entry storage format:

- *block sparse row* format (BSR) and its variations.

For more information see "[Sparse Matrix Storage Formats](#)" in the Appendix A ".

Intel MKL provides auxiliary routines - [matrix converters](#) - that convert sparse matrix from one storage format to another.

Routines and Supported Operations

This section describes operations supported by the Intel Sparse BLAS Level 2 and Level 3 routines. The following notations are used here:

A is a sparse matrix;

B and C are dense matrices;

D is a diagonal scaling matrix;

x and y are dense vectors;

α and β are scalars;

$\text{op}(A)$ is one of the possible operations:

$\text{op}(A) = A$;

$\text{op}(A) = A'$ - transpose of A ;

$\text{op}(A) = \text{conj}(A')$ - conjugated transpose of A .

$\text{inv}(\text{op}(A))$ denotes the inverse of $\text{op}(A)$.

Intel MKL Sparse BLAS Level 2 and Level 3 routines support the following operations:

- computing the vector product between a sparse matrix and a dense vector:

$$y := \alpha * \text{op}(A) * x + \beta * y$$

- solving a single triangular system:

$$y := \alpha * \text{inv}(\text{op}(A)) * x$$

- computing a product between sparse matrix and dense matrix:

$$C := \alpha * \text{op}(A) * B + \beta * C$$

- solving a sparse triangular system with multiple right-hand sides:

$$C := \alpha * \text{inv}(\text{op}(A)) * B$$

Intel MKL provides an additional set of Sparse BLAS Level 2 routines with *simplified interfaces*. Each of these routines operates on a matrix of the fixed type. The following operations are supported:

- computing the vector product between a sparse matrix and a dense vector (for general and symmetric matrices):

$$y := \text{op}(A) * x$$

- solving a single triangular system (for triangular matrices):

$$y := \text{inv}(\text{op}(A)) * x$$

Matrix type is indicated by the field `<mtype>` in the routine name (see section [Naming Conventions in Sparse BLAS Level 2 and Level 3](#)).

NOTE. The routines with simplified interfaces support only four sparse matrix storage formats, specifically:

CSR format in the 3-array variation accepted in the direct sparse solvers and in the CXML;

diagonal format accepted in the CXML;

coordinate format;

BSR format in the 3-array variation.

Note that routines with both typical (conventional) and simplified interfaces use the same computational kernels that work with certain internal data structures.

CAUTION. Intel Sparse BLAS Level 2 and Level 3 routines do not support in-place operations.

Complete list of all routines is given in the [Table 2-9](#) .

Interface Consideration

One-Based and Zero-Based Indexing

The Intel MKL Sparse BLAS Level 2 and Level 3 routines support one-based and zero-based indexing of data arrays.

Routines with typical interfaces support zero-based indexing for the following sparse data storage formats: CSR, CSC, BSR, and COO. Routines with simplified interfaces support zero based indexing for the following sparse data storage formats: CSR, BSR, and COO. See the complete list of [Sparse BLAS Level 2 and Level 3 Routines](#) .

The one-based indexing uses the convention of starting array indices at 1. The zero-based indexing uses the convention of starting array indices at 0. For example, indices of the 5-element array x can be presented in case of one-based indexing as follows:

```
Element index:  1      2      3      4      5
Element value:  1.0  5.0   7.0   8.0   9.0
```

and in case of zero-based indexing as follows:

```
Element index:  0      1      2      3      4
Element value:  1.0  5.0   7.0   8.0   9.0
```

The detailed descriptions of the one-based and zero-based variants of the sparse data storage formats are given in the “[Sparse Matrix Storage Formats](#)” in Appendix A

Most parameters of the routines are identical for both one-based and zero-based indexing, but some of them have certain differences. The following table lists all these differences.

Parameter	One-based Indexing	Zero-based Indexing
<i>val</i>	Array containing non-zero elements of the matrix A , its length is $pntrb(m) - pntrb(1)$.	Array containing non-zero elements of the matrix A , its length is $pntrb(m-1) - pntrb(0)$.
<i>pntrb</i>	Array of length m . This array contains row indices, such that $pntrb(I) - pntrb(1)+1$ is the first index of row I in the arrays <i>val</i> and <i>indx</i>	Array of length m . This array contains row indices, such that $pntrb(I) - pntrb(0)$ is the first index of row I in the arrays <i>val</i> and <i>indx</i> .

Parameter	One-based Indexing	Zero-based Indexing
<i>pntrc</i>	Array of length m . This array contains row indices, such that $pntrc(I) - pntrb(1)$ is the last index of row I in the arrays <i>val</i> and <i>indx</i> .	Array of length m . This array contains row indices, such that $pntrc(I) - pntrb(0) - 1$ is the last index of row I in the arrays <i>val</i> and <i>indx</i> .
<i>ia</i>	Array of length $m + 1$, containing indices of elements in the array <i>a</i> , such that $ia(I)$ is the index in the array <i>a</i> of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one.	Array of length $m+1$, containing indices of elements in the array <i>a</i> , such that $ia(I)$ is the index in the array <i>a</i> of the first non-zero element from the row I . The value of the last element $ia(m)$ is equal to the number of non-zeros.
<i>ldb</i>	Specifies the first dimension of <i>b</i> as declared in the calling (sub)program.	Specifies the second dimension of <i>b</i> as declared in the calling (sub)program.
<i>ldc</i>	Specifies the first dimension of <i>c</i> as declared in the calling (sub)program.	Specifies the second dimension of <i>c</i> as declared in the calling (sub)program.

Difference Between Fortran and C Interfaces

Intel MKL provides both Fortran and C interfaces to all Sparse BLAS Leve2 and Level 3 routines. Parameter descriptions are common for both interfaces with the exception of data types that refer to the FORTRAN 77 standard types. Correspondence between data types specific to the Fortran and C interfaces are given below:

Fortran	C
REAL*4	float
REAL*8	double
INTEGER*4	int
INTEGER*8	long long int
CHARACTER	char

For routines with C interfaces all parameters (including scalars) must be passed by references.

Another difference is how two-dimensional arrays are represented. In Fortran the column-major order is used, and in C - row-major order. This changes the meaning of the parameters *ldb* and *ldc* (see the table above).

Differences Between Intel MKL and NIST* Interfaces

The Intel MKL Sparse BLAS Level 3 routines have the following conventional interfaces:

`mkl_xyyyymm(transa, m, n, k, alpha, matdescra, arg(A), b, ldb, beta, c, ldc)`, for matrix-matrix product;

`mkl_xyyyysm(transa, m, n, alpha, matdescra, arg(A), b, ldb, c, ldc)`, for triangular solvers with multiple right-hand sides.

Here *x* denotes data type, and *yyy* - sparse matrix data structure (storage format).

The analogous NIST* Sparse BLAS (NSB) library routines have the following interfaces:

`xyyyymm(transa, m, n, k, alpha, descra, arg(A), b, ldb, beta, c, ldc, work, lwork)`, for matrix-matrix product;

`xyyyysm(transa, m, n, unitd, dv, alpha, descra, arg(A), b, ldb, beta, c, ldc, work, lwork)`, for triangular solvers with multiple right-hand sides.

Some similar arguments are used in both libraries. The argument *transa* indicates what operation is performed and is slightly different in the NSB library (see [Table 2-5](#)). The arguments *m* and *k* are the number of rows and column in the matrix *A*, respectively, *n* is the number of columns in the matrix *C*. The arguments *alpha* and *beta* are scalar *alpha* and *beta* respectively (*beta* is not used in the Intel MKL triangular solvers.) The arguments *b* and *c* are rectangular arrays with the first dimension *ldb* and *ldc*, respectively. *arg(A)* denotes the list of arguments that describe the sparse representation of *A*.

Table 2-5 Parameter *transa*

	MKL interface	NSB interface	Operation
data type	CHARACTER*1	INTEGER	
value	N or n	0	$op(A) = A$
	T or t	1	$op(A) = A'$
	C or c	2	$op(A) = A'$

Parameter *matdescra*

The parameter *matdescra* describes the relevant characteristic of the matrix *A*. This manual describes *matdescra* as an array of six elements in line with the NIST* implementation. However, only the first four elements of the array are used in the current versions of the Intel MKL Sparse BLAS routines. Elements *matdescra*(5) and *matdescra*(6) are reserved for future use. Note that whether *matdescra* is described in the user's program as an array of length 6 or 4 is of no importance because the array is declared as a pointer in the Intel MKL routines. To learn more about declaration of the *matdescra* array see Sparse BLAS examples located in the following subdirectory of the Intel MKL installation directory: `examples/spblas/`. The table below list elements of the parameter *matdescra*, their values and meanings. The parameter *matdescra* corresponds to the argument *descra* from NSB library.

Table 2-6 Possible Values of the Parameter *matdescra* (*descra*)

	MKL interface		NSB interface	Matrix characteristics
	one-based indexing	zero-based indexing		
data type	CHARACTER	Char	INTEGER	
1st element	<i>matdescra</i> (1)	<i>matdescra</i> (0)	<i>descra</i> (1)	matrix structure
value	G	G	0	general
	S	S	1	symmetric ($A = A'$)
	H	H	2	Hermitian ($A = \text{conjg}(A')$)
	T	T	3	triangular
	A	A	4	skew(anti)-symmetric ($A = -A'$)
	D	D	5	diagonal
2nd element	<i>matdescra</i> (2)	<i>matdescra</i> (1)	<i>descra</i> (2)	upper/lower triangular indicator
value	L	L	1	lower

	MKL interface		NSB interface	Matrix characteristics
	U	U	2	upper
3rd element	<i>matdescra</i> (3)	<i>matdescra</i> (2)	<i>descra</i> (3)	main diagonal type
value	N	N	0	non-unit
	U	U	1	unit
4th element	<i>matdescra</i> (4)	<i>matdescra</i> (3)		type of indexing
value	F			one-based indexing
		C		zero-based indexing

In some cases possible element values of the parameter *matdescra* depend on the values of other elements. The [Table 2-7 "Possible Combinations of Element Values of the Parameter *matdescra*"](#) lists all possible combinations of element values for both multiplication routines and triangular solvers.

Table 2-7 Possible Combinations of Element Values of the Parameter *matdescra*

Routines	<i>matdescra</i> (1)	<i>matdescra</i> (2)	<i>matdescra</i> (3)	<i>matdescra</i> (4)
Multiplication Routines	G	ignored	ignored	F (default) or C
	S or H	L (default)	N (default)	F (default) or C
	S or H	L (default)	U	F (default) or C
	S or H	U	N (default)	F (default) or C
	S or H	U	U	F (default) or C
	A	L (default)	ignored	F (default) or C
	A	U	ignored	F (default) or C
Multiplication Routines and Triangular Solvers	T	L	U	F (default) or C
	T	L	N	F (default) or C

Routines	matdescra(1)	matdescra(2)	matdescra(3)	matdescra(4)
	T	U	U	F (default) or C
	T	U	N	F (default) or C
	D	ignored	N (default)	F (default) or C
	D	ignored	U	F (default) or C

For a matrix in the skyline format with main diagonal declared to be unit, diagonal elements must be stored in the sparse representation even if they are zero. In all other formats diagonal elements can be stored (if needed) in the sparse representation if they are not zero.

Operations with Partial Matrices

One of the distinctive feature of the Intel MKL Sparse BLAS routines is a possibility to perform operations only on partial matrices composed of certain parts (triangles and main diagonal) of the input sparse matrix. It can be done by setting properly first three elements of the parameter *matdescra*.

An arbitrary sparse matrix A can be decomposed as

$$A = L + D + U$$

where L is the strict lower triangle of A , U is the strict upper triangle of A , D is the main diagonal.

Table 2-8 shows correspondence between the output matrices and values of the parameter *matdescra* for the sparse matrix A for multiplication routines.

Table 2-8 Output Matrices for Multiplication Routines

matdescra(1)	matdescra(2)	matdescra(3)	Output Matrix
G	ignored	ignored	$\alpha * \text{op}(A) * x + \beta * y$ $\alpha * \text{op}(A) * B + \beta * C$
S or H	L	N	$\alpha * \text{op}(L+D+L') * x + \beta * y$ $\alpha * \text{op}(L+D+L') * B + \beta * C$
S or H	L	U	$\alpha * \text{op}(L+I+L') * x + \beta * y$ $\alpha * \text{op}(L+I+L') * B + \beta * C$
S or H	U	N	$\alpha * \text{op}(U'+D+U) * x + \beta * y$ $\alpha * \text{op}(U'+D+U) * B + \beta * C$

matdescra(1)	matdescra(2)	matdescra(3)	Output Matrix
S or H	U	U	$\alpha * \text{op}(U' + I + U) * x + \beta * y$ $\alpha * \text{op}(U' + I + U) * B + \beta * C$
T	L	U	$\alpha * \text{op}(L + I) * x + \beta * y$ $\alpha * \text{op}(L + I) * B + \beta * C$
T	L	N	$\alpha * \text{op}(L + D) * x + \beta * y$ $\alpha * \text{op}(L + D) * B + \beta * C$
T	U	U	$\alpha * \text{op}(U + I) * x + \beta * y$ $\alpha * \text{op}(U + I) * B + \beta * C$
T	U	N	$\alpha * \text{op}(U + D) * x + \beta * y$ $\alpha * \text{op}(U + D) * B + \beta * C$
A	L	ignored	$\alpha * \text{op}(L - L') * x + \beta * y$ $\alpha * \text{op}(L - L') * B + \beta * C$
A	U	ignored	$\alpha * \text{op}(U - U') * x + \beta * y$ $\alpha * \text{op}(U - U') * B + \beta * C$
D	ignored	N	$\alpha * D * x + \beta * y$ $\alpha * D * B + \beta * C$
D	ignored	U	$\alpha * x + \beta * y$ $\alpha * B + \beta * C$

Table 2-9 shows correspondence between the output matrices and values of the parameter *matdescra* for the sparse matrix *A* for triangular solvers.

Table 2-9 Output Matrices for Triangular Solvers

matdescra(1)	matdescra(2)	matdescra(3)	Output Matrix

Sparse BLAS Level 2 and Level 3 Routines.

Table 2-9 lists the sparse BLAS Level 2 and Level 3 routines described in more detail later in this section.

Table 2-9 Sparse BLAS Level 2 and Level 3 Routines

Routine/Function	Description
Simplified interface, one-based indexing	
<code>mkl_?csrgev</code>	Computes matrix - vector product of a sparse general matrix in the CSR format (3-array variation)
<code>mkl_?bsrgev</code>	Computes matrix - vector product of a sparse general matrix in the BSR format (3-array variation).
<code>mkl_?coogev</code>	Computes matrix - vector product of a sparse general matrix in the coordinate format.
<code>mkl_?diagm</code>	Computes matrix - vector product of a sparse general matrix in the diagonal format.

Routine/Function	Description
<code>mkl_?csrsv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the CSR format (3-array variation)
<code>mkl_?bsrsv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the BSR format (3-array variation).
<code>mkl_?coosv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the coordinate format.
<code>mkl_?diasv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the diagonal format.
<code>mkl_?csrtrsv</code>	Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation).
<code>mkl_?bsrtrsv</code>	Triangular solver with simplified interface for a sparse matrix in the BSR format (3-array variation).
<code>mkl_?cootrsv</code>	Triangular solvers with simplified interface for a sparse matrix in the coordinate format.
<code>mkl_?diatrsv</code>	Triangular solvers with simplified interface for a sparse matrix in the diagonal format.

Simplified interface, zero-based indexing

<code>mkl_cspblas_?csrsv</code>	Computes matrix - vector product of a sparse general matrix in the CSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_?bsrsv</code>	Computes matrix - vector product of a sparse general matrix in the BSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_?coosv</code>	Computes matrix - vector product of a sparse general matrix in the coordinate format with zero-based indexing.

Routine/Function	Description
<code>mkl_cspblas_?csrsv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the CSR format (3-array variation) with zero-based indexing
<code>mkl_cspblas_?bsrsv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the BSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_?coosv</code>	Computes matrix - vector product of a sparse symmetrical matrix in the coordinate format with zero-based indexing.
<code>mkl_cspblas_?csrtrsv</code>	Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_?bsrtrsv</code>	Triangular solver with simplified interface for a sparse matrix in the BSR format (3-array variation) with zero-based indexing.
<code>mkl_cspblas_?cootrsv</code>	Triangular solver with simplified interface for a sparse matrix in the coordinate format with zero-based indexing.

Typical (conventional) interface, one-based and zero-based indexing

<code>mkl_?csrsv</code>	Computes matrix - vector product of a sparse matrix in the CSR format.
<code>mkl_?bsrsv</code>	Computes matrix - vector product of a sparse matrix in the BSR format.
<code>mkl_?cscsv</code>	Computes matrix - vector product for a sparse matrix in the CSC format.
<code>mkl_?coosv</code>	Computes matrix - vector product for a sparse matrix in the coordinate format.
<code>mkl_?csrsv</code>	Solves a system of linear equations for a sparse matrix in the CSR format.

Routine/Function	Description
<code>mkl_?bsrsv</code>	Solves a system of linear equations for a sparse matrix in the BSR format.
<code>mkl_?cscsv</code>	Solves a system of linear equations for a sparse matrix in the CSC format.
<code>mkl_?coosv</code>	Solves a system of linear equations for a sparse matrix in the coordinate format.
<code>mkl_?csrmm</code>	Computes matrix - matrix product of a sparse matrix in the CSR format
<code>mkl_?bsrmm</code>	Computes matrix - matrix product of a sparse matrix in the BSR format.
<code>mkl_?cscmm</code>	Computes matrix - matrix product of a sparse matrix in the CSC format
<code>mkl_?coomm</code>	Computes matrix - matrix product of a sparse matrix in the coordinate format.
<code>mkl_?csrsm</code>	Solves a system of linear matrix equations for a sparse matrix in the CSR format.
<code>mkl_?bsrsm</code>	Solves a system of linear matrix equations for a sparse matrix in the BSR format.
<code>mkl_?cscsm</code>	Solves a system of linear matrix equations for a sparse matrix in the CSC format.
<code>mkl_?coosm</code>	Solves a system of linear matrix equations for a sparse matrix in the coordinate format.

Typical (conventional) interface, one-based indexing

<code>mkl_?diamv</code>	Computes matrix - vector product of a sparse matrix in the diagonal format.
<code>mkl_?skymv</code>	Computes matrix - vector product for a sparse matrix in the skyline storage format.

Routine/Function	Description
<code>mkl_?diasv</code>	Solves a system of linear equations for a sparse matrix in the diagonal format.
<code>mkl_?skysv</code>	Solves a system of linear equations for a sparse matrix in the skyline format.
<code>mkl_?diamm</code>	Computes matrix - matrix product of a sparse matrix in the diagonal format.
<code>mkl_?skymm</code>	Computes matrix - matrix product of a sparse matrix in the skyline storage format.
<code>mkl_?diasm</code>	Solves a system of linear matrix equations for a sparse matrix in the diagonal format.
<code>mkl_?skysm</code>	Solves a system of linear matrix equations for a sparse matrix in the skyline storage format.
Auxiliary routines	
Matrix converters	
<code>mkl_ddnscsr</code>	Converts a sparse matrix in the dense representation to the CSR format (3-array variation).
<code>mkl_dcsrcoo</code>	Converts a sparse matrix in the CSR format (3-array variation) to the coordinate format and vice versa.
<code>mkl_dcsrbsr</code>	Converts a sparse matrix in the CSR format to the BSR format (3-array variations) and vice versa.
<code>mkl_dcsrsc</code>	Converts a sparse matrix in the CSR format to the CSC and vice versa (3-array variations).
<code>mkl_dcsrdia</code>	Converts a sparse matrix in the CSR format (3-array variation) to the diagonal format and vice versa.
<code>mkl_dcsrsky</code>	Converts a sparse matrix in the CSR format (3-array variation) to the sky line format and vice versa.

Operations on sparse matrices

Routine/Function	Description
<code>mkl_?csradd</code>	Computes the sum of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing.
<code>mkl_?csrmultcsr</code>	Computes the product of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing.
<code>mkl_?csrmultd</code>	Computes product of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing. The result is stored in the dense matrix.

`mkl_?csrgemv`

Computes matrix - vector product of a sparse general matrix stored in the CSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_scsrgemv(transa, m, a, ia, ja, x, y)
call mkl_dcsrgemv(transa, m, a, ia, ja, x, y)
call mkl_ccsrgemv(transa, m, a, ia, ja, x, y)
call mkl_zcsrgemv(transa, m, a, ia, ja, x, y)
```

C:

```
mkl_scsrgemv(&transa, &m, a, ia, ja, x, y);
mkl_dcsrgemv(&transa, &m, a, ia, ja, x, y);
mkl_ccsrgemv(&transa, &m, a, ia, ja, x, y);
mkl_zcsrgemv(&transa, &m, a, ia, ja, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?csrsgemv` routine performs a matrix-vector operation defined as

$$y := A*x$$

or

$$y := A'*x,$$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the CSR format (3-array variation), A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := A'*x$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>a</i>	REAL for <code>mkl_scsrsgemv</code> . DOUBLE PRECISION for <code>mkl_dcsrsgemv</code> . COMPLEX for <code>mkl_ccsrsgemv</code> . DOUBLE COMPLEX for <code>mkl_zcsrsgemv</code> . Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	INTEGER. Array of length $m + 1$, containing indices of elements in the array a , such that $ia(i)$ is the index in the array a of the first non-zero element from the row i . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.

ja INTEGER. Array containing the column indices for each non-zero element of the matrix *A*. Its length is equal to the length of the array *a*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

x REAL for `mkl_scsrgev`.
DOUBLE PRECISION for `mkl_dcscrgev`.
COMPLEX for `mkl_ccscrgev`.
DOUBLE COMPLEX for `mkl_zcscrgev`.
Array, DIMENSION is *m*.
On entry, the array *x* must contain the vector *x*.

Output Parameters

y REAL for `mkl_scsrgev`.
DOUBLE PRECISION for `mkl_dcscrgev`.
COMPLEX for `mkl_ccscrgev`.
DOUBLE COMPLEX for `mkl_zcscrgev`.
Array, DIMENSION at least *m*.
On exit, the array *y* must contain the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_scsrgemv(transa, m, a, ia, ja, x, y)
```

```
  CHARACTER*1  transa
  INTEGER      m
  INTEGER      ia(*), ja(*)
  REAL         a(*), x(*), y(*)
```

```
SUBROUTINE mkl_dcsrgemv(transa, m, a, ia, ja, x, y)
```

```
  CHARACTER*1  transa
  INTEGER      m
  INTEGER      ia(*), ja(*)
  DOUBLE PRECISION  a(*), x(*), y(*)
```

```
SUBROUTINE mkl_ccsrgemv(transa, m, a, ia, ja, x, y)
```

```
  CHARACTER*1  transa
  INTEGER      m
  INTEGER      ia(*), ja(*)
  COMPLEX      a(*), x(*), y(*)
```

```
SUBROUTINE mkl_zcsrgemv(transa, m, a, ia, ja, x, y)
```

```
  CHARACTER*1  transa
  INTEGER      m
  INTEGER      ia(*), ja(*)
  DOUBLE COMPLEX  a(*), x(*), y(*)
```

C:

```
void mkl_scsrgemv(char *transa, int *m, float *a,
int *ia, int *ja, float *x, float *y);
void mkl_dcsrgemv(char *transa, int *m, double *a,
int *ia, int *ja, double *x, double *y);
void mkl_ccsrgemv(char *transa, int *m, MKL_Complex8 *a,
int *ia, int *ja, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zcsrgemv(char *transa, int *m, MKL_Complex16 *a,
int *ia, int *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?bsrgemv

Computes matrix - vector product of a sparse general matrix stored in the BSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_sbsrgemv(transa, m, lb, a, ia, ja, x, y)
call mkl_dbsrgemv(transa, m, lb, a, ia, ja, x, y)
call mkl_cbsrgemv(transa, m, lb, a, ia, ja, x, y)
call mkl_zbsrgemv(transa, m, lb, a, ia, ja, x, y)
```

C:

```
mkl_sbsrgemv(&transa, &m, &lb, a, ia, ja, x, y);
mkl_dbsrgemv(&transa, &m, &lb, a, ia, ja, x, y);
mkl_cbsrgemv(&transa, &m, &lb, a, ia, ja, x, y);
mkl_zbsrgemv(&transa, &m, &lb, a, ia, ja, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mk1_?bsrgemv` routine performs a matrix-vector operation defined as

$$y := A*x$$

or

$$y := A'*x,$$

where:

x and y are vectors,

A is an m -by- m block sparse square matrix in the BSR format (3-array variation), A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A'*x$,
<i>m</i>	INTEGER. Number of block rows of the matrix A .
<i>lb</i>	INTEGER. Size of the block in the matrix A .
<i>a</i>	REAL for <code>mk1_sbsrgemv</code> . DOUBLE PRECISION for <code>mk1_dbsrgemv</code> . COMPLEX for <code>mk1_cbsrgemv</code> . DOUBLE COMPLEX for <code>mk1_zbsrgemv</code> . Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb*lb$. Refer to <i>values</i> array description in BSR Format for more details.
<i>ia</i>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array a , such that $ia(i)$ is the index in the array a of the first non-zero element from the row i . The

	value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks plus one. Refer to <i>rowIndex</i> array description in BSR Format for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks of the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details.
<i>x</i>	REAL for <code>mkl_sbsrgemv</code> . DOUBLE PRECISION for <code>mkl_dbsrgemv</code> . COMPLEX for <code>mkl_cbsrgemv</code> . DOUBLE COMPLEX for <code>mkl_zbsrgemv</code> . Array, DIMENSION ($m * lb$). On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL for <code>mkl_sbsrgemv</code> . DOUBLE PRECISION for <code>mkl_dbsrgemv</code> . COMPLEX for <code>mkl_cbsrgemv</code> . DOUBLE COMPLEX for <code>mkl_zbsrgemv</code> . Array, DIMENSION at least ($m * lb$). On exit, the array <i>y</i> must contain the vector <i>y</i> .

int *ia, int *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?coogemv

Computes matrix-vector product of a sparse general matrix stored in the coordinate format with one-based indexing.

Syntax

Fortran:

```
call mkl_scoogemv(transa, m, val, rowind, colind, nnz, x, y)
call mkl_dcoogemv(transa, m, val, rowind, colind, nnz, x, y)
call mkl_ccoogemv(transa, m, val, rowind, colind, nnz, x, y)
call mkl_zcoogemv(transa, m, val, rowind, colind, nnz, x, y)
```

C:

```
mkl_scoogemv(&transa, &m, val, rowind, colind, &nnz, x, y);
mkl_dcoogemv(&transa, &m, val, rowind, colind, &nnz, x, y);
mkl_ccoogemv(&transa, &m, val, rowind, colind, &nnz, x, y);
mkl_zcoogemv(&transa, &m, val, rowind, colind, &nnz, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?coogemv` routine performs a matrix-vector operation defined as

$$y := A*x$$

or

$$y := A'*x,$$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the coordinate format, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A'*x$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>val</i>	REAL for <code>mkl_scoogemv</code> . DOUBLE PRECISION for <code>mkl_dcoogemv</code> . COMPLEX for <code>mkl_ccoogemv</code> . DOUBLE COMPLEX for <code>mkl_zcoogemv</code> . Array of length <i>nnz</i> , contains non-zero elements of the matrix A in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix A . Refer to <i>rows</i> array description in Coordinate Format for more details.

<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>x</i>	REAL for mkl_scoogemv. DOUBLE PRECISION for mkl_dcoogemv. COMPLEX for mkl_ccoogemv. DOUBLE COMPLEX for mkl_zcoogemv. Array, DIMENSION is <i>m</i> . One entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL for mkl_scoogemv. DOUBLE PRECISION for mkl_dcoogemv. COMPLEX for mkl_ccoogemv. DOUBLE COMPLEX for mkl_zcoogemv. Array, DIMENSION at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> .

```

mkl_?diagemv

Computes matrix - vector product of a sparse general matrix stored in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_sdiagemv(transa, m, val, lval, idiag, ndiag, x, y)
call mkl_ddiagemv(transa, m, val, lval, idiag, ndiag, x, y)
call mkl_cdiagemv(transa, m, val, lval, idiag, ndiag, x, y)
call mkl_zdiagemv(transa, m, val, lval, idiag, ndiag, x, y)
```

C:

```
mkl_sdiagemv(&transa, &m, val, &lval, idiag, &ndiag, x, y);
mkl_ddiagemv(&transa, &m, val, &lval, idiag, &ndiag, x, y);
mkl_cdiagemv(&transa, &m, val, &lval, idiag, &ndiag, x, y);
mkl_zdiagemv(&transa, &m, val, &lval, idiag, &ndiag, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?diagemv` routine performs a matrix-vector operation defined as

$$y := A*x$$

or

$$y := A'*x,$$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the diagonal storage format, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := A'*x$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>val</i>	REAL for <code>mkl_sdiagemv</code> . DOUBLE PRECISION for <code>mkl_ddiagemv</code> . COMPLEX for <code>mkl_ccsrgemv</code> . DOUBLE COMPLEX for <code>mkl_zdiagemv</code> . Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix A . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix A . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details.

ndiag INTEGER. Specifies the number of non-zero diagonals of the matrix *A*.

x REAL for `mkl_sdiagemv`.
DOUBLE PRECISION for `mkl_ddiagemv`.
COMPLEX for `mkl_ccsrgemv`.
DOUBLE COMPLEX for `mkl_zdiagemv`.
Array, DIMENSION is *m*.
On entry, the array *x* must contain the vector *x*.

Output Parameters

y REAL for `mkl_sdiagemv`.
DOUBLE PRECISION for `mkl_ddiagemv`.
COMPLEX for `mkl_ccsrgemv`.
DOUBLE COMPLEX for `mkl_zdiagemv`.
Array, DIMENSION at least *m*.
On exit, the array *y* must contain the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_sdiagmv(transa, m, val, lval, idiag, ndiag, x, y)
```

```
  CHARACTER*1  transa

```

mkl_?csrsvmv

Computes matrix - vector product of a sparse symmetrical matrix stored in the CSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_scsrsvmv(uplo, m, a, ia, ja, x, y)
call mkl_dcsrsvmv(uplo, m, a, ia, ja, x, y)
call mkl_ccsrsvmv(uplo, m, a, ia, ja, x, y)
call mkl_zcsrsvmv(uplo, m, a, ia, ja, x, y)
```

C:

```
mkl_scsrsvmv(&uplo, &m, a, ia, ja, x, y);
mkl_dcsrsvmv(&uplo, &m, a, ia, ja, x, y);
mkl_ccsrsvmv(&uplo, &m, a, ia, ja, x, y);
mkl_zcsrsvmv(&uplo, &m, a, ia, ja, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?csrsvmv` routine performs a matrix-vector operation defined as

$$y := A*x$$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the CSR format (3-array variation).

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used.</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.</p>
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>a</i>	<p>REAL for <code>mkl_scsrsvmv</code>.</p> <p>DOUBLE PRECISION for <code>mkl_dcsrsvmv</code>.</p> <p>COMPLEX for <code>mkl_ccsrsvmv</code>.</p> <p>DOUBLE COMPLEX for <code>mkl_zcsrsvmv</code>.</p> <p>Array containing non-zero elements of the matrix A. Its length is equal to the number of non-zero elements in the matrix A. Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.</p>
<i>ia</i>	<p>INTEGER. Array of length $m + 1$, containing indices of elements in the array a, such that $ia(i)$ is the index in the array a of the first non-zero element from the row i. The</p>

	value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>a</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>x</i>	REAL for mkl_scsrsvmv. DOUBLE PRECISION for mkl_dcsrsvmv. COMPLEX for mkl_ccsrsvmv. DOUBLE COMPLEX for mkl_zcsrsvmv. Array, DIMENSION is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL for mkl_scsrsvmv. DOUBLE PRECISION for mkl_dcsrsvmv. COMPLEX for mkl_ccsrsvmv. DOUBLE COMPLEX for mkl_zcsrsvmv. Array, DIMENSION at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> .

    int *ia, int *ja, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?bsrsvmv

Computes matrix-vector product of a sparse symmetrical matrix stored in the BSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_sbsrsvmv(uplo, m, lb, a, ia, ja, x, y)
call mkl_dbsrsvmv(uplo, m, lb, a, ia, ja, x, y)
call mkl_cbsrsvmv(uplo, m, lb, a, ia, ja, x, y)
call mkl_zbsrsvmv(uplo, m, lb, a, ia, ja, x, y)
```

C:

```
mkl_sbsrsvmv(&uplo, &m, &lb, a, ia, ja, x, y);
mkl_dbsrsvmv(&uplo, &m, &lb, a, ia, ja, x, y);
mkl_cbsrsvmv(&uplo, &m, &lb, a, ia, ja, x, y);
mkl_zbsrsvmv(&uplo, &m, &lb, a, ia, ja, x, y);
```

Description

This routine is declared in `mkl_spbblas.fi` for FORTRAN 77 interface and in `mkl_spbblas.h` for C interface.

The `mkl_?bsrsymv` routine performs a matrix-vector operation defined as

$$y := A*x$$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the BSR format (3-array variation).

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is considered. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>m</i>	INTEGER. Number of block rows of the matrix A .
<i>lb</i>	INTEGER. Size of the block in the matrix A .
<i>a</i>	REAL for <code>mkl_sbsrsymv</code> . DOUBLE PRECISION for <code>mkl_dbsrsymv</code> . COMPLEX for <code>mkl_cbsrsymv</code> . DOUBLE COMPLEX for <code>mkl_zcsrgemv</code> . Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb*lb$. Refer to <i>values</i> array description in BSR Format for more details.
<i>ia</i>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array a , such that $ia(i)$ is the index in the array a of the first non-zero element from the row i . The

	value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks plus one. Refer to <i>rowIndex</i> array description in BSR Format for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks of the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details.
<i>x</i>	REAL for <code>mkl_sbsrsymv</code> . DOUBLE PRECISION for <code>mkl_dbsrsymv</code> . COMPLEX for <code>mkl_cbsrsymv</code> . DOUBLE COMPLEX for <code>mkl_zcsrgemv</code> . Array, DIMENSION ($m * lb$). On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL for <code>mkl_sbsrsymv</code> . DOUBLE PRECISION for <code>mkl_dbsrsymv</code> . COMPLEX for <code>mkl_cbsrsymv</code> . DOUBLE COMPLEX for <code>mkl_zcsrgemv</code> . Array, DIMENSION at least ($m * lb$). On exit, the array <i>y</i> must contain the vector <i>y</i> .
----------	--

```

mkl_?coosymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the coordinate format with one-based indexing.

Syntax

Fortran:

```
call mkl_scoosymv(uplo, m, val, rowind, colind, nnz, x, y)
call mkl_dcoosymv(uplo, m, val, rowind, colind, nnz, x, y)
call mkl_ccoosymv(uplo, m, val, rowind, colind, nnz, x, y)
call mkl_zcoosymv(uplo, m, val, rowind, colind, nnz, x, y)
```

C:

```
mkl_scoosymv(&uplo, &m, val, rowind, colind, &nnz, x, y);
mkl_dcoosymv(&uplo, &m, val, rowind, colind, &nnz, x, y);
mkl_ccoosymv(&uplo, &m, val, rowind, colind, &nnz, x, y);
mkl_zcoosymv(&uplo, &m, val, rowind, colind, &nnz, x, y);
```

Description

This routine is declared in `mkl_spbblas.fi` for FORTRAN 77 interface and in `mkl_spbblas.h` for C interface.

The `mk1_?coosymv` routine performs a matrix-vector operation defined as

$$y := A*x$$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the coordinate format.

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>val</i>	REAL for <code>mk1_scoosymv</code> . DOUBLE PRECISION for <code>mk1_dcoosymv</code> . COMPLEX for <code>mk1_ccoosymv</code> . DOUBLE COMPLEX for <code>mk1_zcoosymv</code> . Array of length <i>nnz</i> , contains non-zero elements of the matrix A in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix A . Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix A . Refer to <i>columns</i> array description in Coordinate Format for more details.

nnz INTEGER. Specifies the number of non-zero element of the matrix *A*.
Refer to *nnz* description in [Coordinate Format](#) for more details.

x REAL for `mkl_scoosymv`.
DOUBLE PRECISION for `mkl_dcoosymv`.
COMPLEX for `mkl_ccoosymv`.
DOUBLE COMPLEX for `mkl_zcoosymv`.
Array, DIMENSION is *m*.
On entry, the array *x* must contain the vector *x*.

Output Parameters

y REAL for `mkl_scoosymv`.
DOUBLE PRECISION for `mkl_dcoosymv`.
COMPLEX for `mkl_ccoosymv`.
DOUBLE COMPLEX for `mkl_zcoosymv`.
Array, DIMENSION at least *m*.
On exit, the array *y* must contain the vector *y*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_scoosymv(uplo, m, val, rowind, colind, nnz, x, y)
```

```

int *colind, int *nnz, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?diasymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_sdiasymv(uplo, m, val, lval, iddiag, ndiag, x, y)  
call mkl_ddiasymv(uplo, m, val, lval, iddiag, ndiag, x, y)  
call mkl_cdiasymv(uplo, m, val, lval, iddiag, ndiag, x, y)  
call mkl_zdiasymv(uplo, m, val, lval, iddiag, ndiag, x, y)
```

C:

```
mkl_sdiasymv(&uplo, &m, val, &lval, iddiag, &ndiag, x, y);  
mkl_ddiasymv(&uplo, &m, val, &lval, iddiag, &ndiag, x, y);  
mkl_cdiasymv(&uplo, &m, val, &lval, iddiag, &ndiag, x, y);  
mkl_zdiasymv(&uplo, &m, val, &lval, iddiag, &ndiag, x, y);
```

Description

This routine is declared in `mkl_spbblas.fi` for FORTRAN 77 interface and in `mkl_spbblas.h` for C interface.

The `mkl_?diasymv` routine performs a matrix-vector operation defined as

$$y := A*x$$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix.

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>val</i>	REAL for <code>mkl_sdiasymv</code> . DOUBLE PRECISION for <code>mkl_ddiasymv</code> . COMPLEX for <code>mkl_cdiasymv</code> . DOUBLE COMPLEX for <code>mkl_zdiasymv</code> . Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix A . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix A . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details.

ndiag INTEGER. Specifies the number of non-zero diagonals of the matrix *A*.

x REAL for `mkl_sdiasymv`.
DOUBLE PRECISION for `mkl_ddiasymv`.
COMPLEX for `mkl_cdiasymv`.
DOUBLE COMPLEX for `mkl_zdiasymv`.
Array, DIMENSION is *m*.
On entry, the array *x* must contain the vector *x*.

Output Parameters

y REAL for `mkl_sdiasymv`.
DOUBLE PRECISION for `mkl_ddiasymv`.
COMPLEX for `mkl_cdiasymv`.
DOUBLE COMPLEX for `mkl_zdiasymv`.
Array, DIMENSION at least *m*.
On exit, the array *y* must contain the vector *y*.

Interfaces

```

mkl_?csrtrsv

Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_scsrtrsv(uplo, transa, diag, m, a, ia, ja, x, y)
call mkl_dcsrtrsv(uplo, transa, diag, m, a, ia, ja, x, y)
call mkl_ccsrtrsv(uplo, transa, diag, m, a, ia, ja, x, y)
call mkl_zcsrtrsv(uplo, transa, diag, m, a, ia, ja, x, y)
```

C:

```
mkl_scsrtrsv(&uplo, &transa, &diag, &m, a, ia, ja, x, y);
mkl_dcsrtrsv(&uplo, &transa, &diag, &m, a, ia, ja, x, y);
mkl_ccsrtrsv(&uplo, &transa, &diag, &m, a, ia, ja, x, y);
mkl_zcsrtrsv(&uplo, &transa, &diag, &m, a, ia, ja, x, y);
```

Description

This routine is declared in `mkl_spbblas.fi` for FORTRAN 77 interface and in `mkl_spbblas.h` for C interface.

The `mkl_?csrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the CSR format (3 array variation):

$$A*y = x$$

or

$$A'*y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A'*y = x$,
<i>diag</i>	CHARACTER*1. Specifies whether A is unit triangular. If <i>diag</i> = 'U' or 'u', then A is a unit triangular. If <i>diag</i> = 'N' or 'n', then A is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>a</i>	REAL for <code>mkl_scsrtrmv</code> . DOUBLE PRECISION for <code>mkl_dcsrtrmv</code> . COMPLEX for <code>mkl_ccsrtrmv</code> . DOUBLE COMPLEX for <code>mkl_zcsrtrmv</code> .

Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

NOTE. The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

ia INTEGER. Array of length $m + 1$, containing indices of elements in the array *a*, such that $ia(i)$ is the index in the array *a* of the first non-zero element from the row *i*. The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

ja INTEGER. Array containing the column indices for each non-zero element of the matrix A . Its length is equal to the length of the array *a*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

NOTE. Column indices must be sorted in increasing order for each row.

x REAL for `mkl_scsrtrmv`.
 DOUBLE PRECISION for `mkl_dcsrtrmv`.
 COMPLEX for `mkl_ccsrtrmv`.
 DOUBLE COMPLEX for `mkl_zcsrtrmv`.
 Array, DIMENSION is *m*.
 On entry, the array *x* must contain the vector *x*.

Output Parameters

y REAL for mkl_scsrtrmv.
 DOUBLE PRECISION for mkl_dcsrtrmv.
 COMPLEX for mkl_ccsrtrmv.
 DOUBLE COMPLEX for mkl_zcsrtrmv.
 Array, DIMENSION at least m .
 Contains the vector y .

```

mkl_?bsrtrsv

Triangular solver with simplified interface for a sparse matrix stored in the BSR format (3-array variation) with one-based indexing.

Syntax**Fortran:**

```

call mkl_sbsrtrsv(uplo, transa, diag, m, lb, a, ia, ja, x, y)
call mkl_dbsrtrsv(uplo, transa, diag, m, lb, a, ia, ja, x, y)
call mkl_cbsrtrsv(uplo, transa, diag, m, lb, a, ia, ja, x, y)
call mkl_zbsrtrsv(uplo, transa, diag, m, lb, a, ia, ja, x, y)

```

C:

```

mkl_sbsrtrsv(&uplo, &transa, &diag, &m, &lb, a, ia, ja, x, y);
mkl_dbsrtrsv(&uplo, &transa, &diag, &m, &lb, a, ia, ja, x, y);
mkl_cbsrtrsv(&uplo, &transa, &diag, &m, &lb, a, ia, ja, x, y);
mkl_zbsrtrsv(&uplo, &transa, &diag, &m, &lb, a, ia, ja, x, y);

```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?bsrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the BSR format (3-array variation) :

$y := A*x$

or

$y := A'*x,$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A'*x$.
<i>diag</i>	CHARACTER*1. Specifies whether A is a unit triangular matrix. If <i>diag</i> = 'U' or 'u', then A is a unit triangular. If <i>diag</i> = 'N' or 'n', then A is not a unit triangular.
<i>m</i>	INTEGER. Number of block rows of the matrix A .
<i>lb</i>	INTEGER. Size of the block in the matrix A .

a REAL for `mkl_sbsrtrsv`.
 DOUBLE PRECISION for `mkl_dbsrtrsv`.
 COMPLEX for `mkl_cbsrtrsv`.
 DOUBLE COMPLEX for `mkl_zbsrtrsv`.
 Array containing elements of non-zero blocks of the matrix *A*. Its length is equal to the number of non-zero blocks in the matrix *A* multiplied by $lb * lb$. Refer to *values* array description in [BSR Format](#) for more details.

NOTE. The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

ia INTEGER. Array of length $(m + 1)$, containing indices of block in the array *a*, such that $ia(I)$ is the index in the array *a* of the first non-zero element from the row *I*. The value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks plus one. Refer to *rowIndex* array description in [BSR Format](#) for more details.

ja INTEGER.
 Array containing the column indices for each non-zero block in the matrix *A*.
 Its length is equal to the number of non-zero blocks of the matrix *A*. Refer to *columns* array description in [BSR Format](#) for more details.

x REAL for `mkl_sbsrtrsv`.
 DOUBLE PRECISION for `mkl_dbsrtrsv`.
 COMPLEX for `mkl_cbsrtrsv`.
 DOUBLE COMPLEX for `mkl_zbsrtrsv`.
 Array, DIMENSION $(m * lb)$.
 On entry, the array *x* must contain the vector *x*.

Output Parameters

y

- REAL for `mkl_sbsrtrsv`.
- DOUBLE PRECISION for `mkl_dbsrtrsv`.
- COMPLEX for `mkl_cbsrtrsv`.
- DOUBLE COMPLEX for `mkl_zbsrtrsv`.

Array, DIMENSION at least $(m*lb)$.
On exit, the array y must contain the vector y .

Interfaces

```

mkl_?cootrsv

Triangular solvers with simplified interface for a sparse matrix in the coordinate format with one-based indexing.

Syntax

Fortran:

```
call mkl_scootrsv(uplo, transa, diag, m, val, rowind, colind, nnz, x, y)
call mkl_dcootrsv(uplo, transa, diag, m, val, rowind, colind, nnz, x, y)
call mkl_ccootrsv(uplo, transa, diag, m, val, rowind, colind, nnz, x, y)
call mkl_zcootrsv(uplo, transa, diag, m, val, rowind, colind, nnz, x, y)
```

C:

```
mkl_scootrsv(&uplo, &transa, &diag, &m, val, rowind, colind, &nnz, x, y);
mkl_dcootrsv(&uplo, &transa, &diag, &m, val, rowind, colind, &nnz, x, y);
mkl_ccootrsv(&uplo, &transa, &diag, &m, val, rowind, colind, &nnz, x, y);
mkl_zcootrsv(&uplo, &transa, &diag, &m, val, rowind, colind, &nnz, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?cootrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the coordinate format:

$$A*y = x$$

or

$$A'*y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is considered. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A'*y = x$,
<i>diag</i>	CHARACTER*1. Specifies whether A is unit triangular. If <i>diag</i> = 'U' or 'u', then A is unit triangular. If <i>diag</i> = 'N' or 'n', then A is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>val</i>	REAL for <code>mkl_scootrsv</code> . DOUBLE PRECISION for <code>mkl_dcootrsv</code> . COMPLEX for <code>mkl_ccootrsv</code> . DOUBLE COMPLEX for <code>mkl_zcootrsv</code> .

	<p>Array of length <i>nnz</i>, contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.</p>

*y);
```

mkl_?diatrsv

Triangular solvers with simplified interface for a sparse matrix in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_sdiatrsv(uplo, transa, diag, m, val, lval, idiag, ndiag, x, y)
call mkl_ddiatrsv(uplo, transa, diag, m, val, lval, idiag, ndiag, x, y)
call mkl_cdiatrsv(uplo, transa, diag, m, val, lval, idiag, ndiag, x, y)
call mkl_zdiatrsv(uplo, transa, diag, m, val, lval, idiag, ndiag, x, y)
```

C:

```
mkl_sdiatrsv(&uplo, &transa, &diag, &m, val, &lval, idiag, &ndiag, x, y);
mkl_ddiatrsv(&uplo, &transa, &diag, &m, val, &lval, idiag, &ndiag, x, y);
mkl_cdiatrsv(&uplo, &transa, &diag, &m, val, &lval, idiag, &ndiag, x, y);
mkl_zdiatrsv(&uplo, &transa, &diag, &m, val, &lval, idiag, &ndiag, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?diatrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the diagonal format:

$$A*y = x$$

or

$$A'*y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section **"Interfaces"** below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A'*y = x$,
<i>diag</i>	CHARACTER*1. Specifies whether A is unit triangular. If <i>diag</i> = 'U' or 'u', then A is unit triangular. If <i>diag</i> = 'N' or 'n', then A is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix A .

<i>val</i>	REAL for <code>mkl_sdiatrsv</code> . DOUBLE PRECISION for <code>mkl_ddiatrsv</code> . COMPLEX for <code>mkl_cdiatrsv</code> . DOUBLE COMPLEX for <code>mkl_zdiatrsv</code> . Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix A. Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix A.

NOTE. All elements of this array must be sorted in increasing order.

Refer to *distance* array description in [Diagonal Storage Scheme](#) for more details.

<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix A.
<i>x</i>	REAL for <code>mkl_sdiatrsv</code> . DOUBLE PRECISION for <code>mkl_ddiatrsv</code> . COMPLEX for <code>mkl_cdiatrsv</code> . DOUBLE COMPLEX for <code>mkl_zdiatrsv</code> . Array, DIMENSION is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL for <code>mkl_sdiatrsv</code> . DOUBLE PRECISION for <code>mkl_ddiatrsv</code> . COMPLEX for <code>mkl_cdiatrsv</code> . DOUBLE COMPLEX for <code>mkl_zdiatrsv</code> . Array, DIMENSION at least <i>m</i> . Contains the vector <i>y</i> .

```

mkl_cspblas_?csrgermv

Computes matrix - vector product of a sparse general matrix stored in the CSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_scsrgermv(transa, m, a, ia, ja, x, y)
call mkl_cspblas_dcsrgermv(transa, m, a, ia, ja, x, y)
call mkl_cspblas_ccsrgermv(transa, m, a, ia, ja, x, y)
call mkl_cspblas_zcsrgermv(transa, m, a, ia, ja, x, y)
```

C:

```
mkl_cspblas_scsrgermv(&transa, &m, a, ia, ja, x, y);
mkl_cspblas_dcsrgermv(&transa, &m, a, ia, ja, x, y);
mkl_cspblas_ccsrgermv(&transa, &m, a, ia, ja, x, y);
mkl_cspblas_zcsrgermv(&transa, &m, a, ia, ja, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_cspblas_?csrgev` routine performs a matrix-vector operation defined as

$$y := A*x$$

or

$$y := A'*x,$$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the CSR format (3-array variation) with zero-based indexing, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A'*x$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>a</i>	REAL for <code>mkl_cspblas_scsrgev</code> . DOUBLE PRECISION for <code>mkl_cspblas_dcsrgev</code> . COMPLEX for <code>mkl_cspblas_ccsrgev</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zcsrgev</code> . Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.

<i>ia</i>	INTEGER. Array of length $m + 1$, containing indices of elements in the array <i>a</i> , such that $ia(I)$ is the index in the array <i>a</i> of the first non-zero element from the row <i>I</i> . The value of the last element $ia(m)$ is equal to the number of non-zeros. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>a</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>x</i>	REAL for <code>mkl_cspblas_scsrgemv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dcsrgemv</code> . COMPLEX for <code>mkl_cspblas_ccsrgemv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zcsrgemv</code> . Array, DIMENSION is <i>m</i> . One entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL for <code>mkl_cspblas_scsrgemv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dcsrgemv</code> . COMPLEX for <code>mkl_cspblas_ccsrgemv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zcsrgemv</code> . Array, DIMENSION at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> .
----------	---

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_cspblas_scsrgemv(transa, m, a, ia, ja, x, y)
```

```

mkl_cspblas_?bsrgemv

Computes matrix - vector product of a sparse general matrix stored in the BSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_sbsrgemv(transa, m, lb, a, ia, ja, x, y)
call mkl_cspblas_dbsrgemv(transa, m, lb, a, ia, ja, x, y)
call mkl_cspblas_cbsrgemv(transa, m, lb, a, ia, ja, x, y)
call mkl_cspblas_zbsrgemv(transa, m, lb, a, ia, ja, x, y)
```

C:

```
mkl_cspblas_sbsrgemv(&transa, &m, &lb, a, ia, ja, x, y);
mkl_cspblas_dbsrgemv(&transa, &m, &lb, a, ia, ja, x, y);
mkl_cspblas_cbsrgemv(&transa, &m, &lb, a, ia, ja, x, y);
mkl_cspblas_zbsrgemv(&transa, &m, &lb, a, ia, ja, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_cspblas_?bsrgemv` routine performs a matrix-vector operation defined as

$$y := A*x$$

or

$$y := A'*x,$$

where:

x and y are vectors,

A is an m -by- m block sparse square matrix in the BSR format (3-array variation) with zero-based indexing, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A'*x$,
<i>m</i>	INTEGER. Number of block rows of the matrix A .
<i>lb</i>	INTEGER. Size of the block in the matrix A .
<i>a</i>	REAL for <code>mkl_cspblas_sbsrgemv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dbsrgemv</code> . COMPLEX for <code>mkl_cspblas_cbsrgemv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zbsrgemv</code> . Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb*lb$. Refer to <i>values</i> array description in BSR Format for more details.
<i>ia</i>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array a , such that $ia(i)$ is the index in the array a of the first non-zero element from the row i . The

	value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks. Refer to <i>rowIndex</i> array description in BSR Format for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks of the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details.
<i>x</i>	REAL for <code>mkl_cspblas_sbsrgemv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dbsrgemv</code> . COMPLEX for <code>mkl_cspblas_cbsrgemv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zbsrgemv</code> . Array, DIMENSION ($m * lb$). On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL for <code>mkl_cspblas_sbsrgemv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dbsrgemv</code> . COMPLEX for <code>mkl_cspblas_cbsrgemv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zbsrgemv</code> . Array, DIMENSION at least ($m * lb$). On exit, the array <i>y</i> must contain the vector <i>y</i> .

```

mkl_cspblas_?coogemv

Computes matrix - vector product of a sparse general matrix stored in the coordinate format with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_scoogemv(transa, m, val, rowind, colind, nnz, x, y)
call mkl_cspblas_dcoogemv(transa, m, val, rowind, colind, nnz, x, y)
call mkl_cspblas_ccoogemv(transa, m, val, rowind, colind, nnz, x, y)
call mkl_cspblas_zcoogemv(transa, m, val, rowind, colind, nnz, x, y)
```

C:

```
mkl_cspblas_scoogemv(&transa, &m, val, rowind, colind, &nnz, x, y);
mkl_cspblas_dcoogemv(&transa, &m, val, rowind, colind, &nnz, x, y);
mkl_cspblas_ccoogemv(&transa, &m, val, rowind, colind, &nnz, x, y);
mkl_cspblas_zcoogemv(&transa, &m, val, rowind, colind, &nnz, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_cspblas_dcoogemv` routine performs a matrix-vector operation defined as

$$y := A*x$$

or

$$y := A'*x,$$

where:

x and y are vectors,

A is an m -by- m sparse square matrix in the coordinate format with zero-based indexing, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A'*x$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>val</i>	REAL for <code>mkl_cspblas_scoogemv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dcoogemv</code> . COMPLEX for <code>mkl_cspblas_ccoogemv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zcoogemv</code> . Array of length <i>nnz</i> , contains non-zero elements of the matrix A in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix A . Refer to <i>rows</i> array description in Coordinate Format for more details.

<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>x</i>	REAL for <code>mkl_cspblas_scoogemv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dcoogemv</code> . COMPLEX for <code>mkl_cspblas_ccoogemv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zcoogemv</code> . Array, DIMENSION is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL for <code>mkl_cspblas_scoogemv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dcoogemv</code> . COMPLEX for <code>mkl_cspblas_ccoogemv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zcoogemv</code> . Array, DIMENSION at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> .

```

mkl_cspblas_?csrsvmv

Computes matrix-vector product of a sparse symmetrical matrix stored in the CSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_scsrsvmv(uplo, m, a, ia, ja, x, y)  
call mkl_cspblas_dcsrsvmv(uplo, m, a, ia, ja, x, y)  
call mkl_cspblas_ccsrsvmv(uplo, m, a, ia, ja, x, y)  
call mkl_cspblas_zcsrsvmv(uplo, m, a, ia, ja, x, y)
```

C:

```
mkl_cspblas_scsrsvmv(&uplo, &m, a, ia, ja, x, y);  
mkl_cspblas_dcsrsvmv(&uplo, &m, a, ia, ja, x, y);  
mkl_cspblas_ccsrsvmv(&uplo, &m, a, ia, ja, x, y);  
mkl_cspblas_zcsrsvmv(&uplo, &m, a, ia, ja, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_cspblas_?csrsvmv` routine performs a matrix-vector operation defined as

$$y := A*x$$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the CSR format (3-array variation) with zero-based indexing.

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	<p>CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used.</p> <p>If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used.</p> <p>If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.</p>

```

mkl_cspblas_?bsrsymv

Computes matrix-vector product of a sparse symmetrical matrix stored in the BSR format (3-arrays variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_sbsrsymv(uplo, m, lb, a, ia, ja, x, y)
call mkl_cspblas_dbsrsymv(uplo, m, lb, a, ia, ja, x, y)
call mkl_cspblas_cbsrsymv(uplo, m, lb, a, ia, ja, x, y)
call mkl_cspblas_zbsrsymv(uplo, m, lb, a, ia, ja, x, y)
```

C:

```
mkl_cspblas_sbsrsymv(&uplo, &m, &lb, a, ia, ja, x, y);
mkl_cspblas_dbsrsymv(&uplo, &m, &lb, a, ia, ja, x, y);
mkl_cspblas_cbsrsymv(&uplo, &m, &lb, a, ia, ja, x, y);
mkl_cspblas_zbsrsymv(&uplo, &m, &lb, a, ia, ja, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_cspblas_?bsrsymv` routine performs a matrix-vector operation defined as

$$y := A*x$$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the BSR format (3-array variation) with zero-based indexing.

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>m</i>	INTEGER. Number of block rows of the matrix A .
<i>lb</i>	INTEGER. Size of the block in the matrix A .
<i>a</i>	REAL for <code>mkl_cspblas_sbsrsymv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dbsrsymv</code> . COMPLEX for <code>mkl_cspblas_cbsrsymv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zbsrsymv</code> . Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $lb*lb$. Refer to <i>values</i> array description in BSR Format for more details.
<i>ia</i>	INTEGER. Array of length $(m + 1)$, containing indices of block in the array a , such that $ia(i)$ is the index in the array a of the first non-zero element from the row i . The

	value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks plus one. Refer to <i>rowIndex</i> array description in BSR Format for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks of the matrix <i>A</i> . Refer to <i>columns</i> array description in BSR Format for more details.
<i>x</i>	REAL for <code>mkl_cspblas_sbsrsymv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dbsrsymv</code> . COMPLEX for <code>mkl_cspblas_cbsrsymv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zbsrsymv</code> . Array, DIMENSION ($m * lb$). On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL for <code>mkl_cspblas_sbsrsymv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dbsrsymv</code> . COMPLEX for <code>mkl_cspblas_cbsrsymv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zbsrsymv</code> . Array, DIMENSION at least ($m * lb$). On exit, the array <i>y</i> must contain the vector <i>y</i> .

```

mkl_cspblas_?coosymv

Computes matrix - vector product of a sparse symmetrical matrix stored in the coordinate format with zero-based indexing .

Syntax

Fortran:

```
call mkl_cspblas_scoosymv(uplo, m, val, rowind, colind, nnz, x, y)
call mkl_cspblas_dcoosymv(uplo, m, val, rowind, colind, nnz, x, y)
call mkl_cspblas_ccoosymv(uplo, m, val, rowind, colind, nnz, x, y)
call mkl_cspblas_zcoosymv(uplo, m, val, rowind, colind, nnz, x, y)
```

C:

```
mkl_cspblas_scoosymv(&uplo, &m, val, rowind, colind, &nnz, x, y);
mkl_cspblas_dcoosymv(&uplo, &m, val, rowind, colind, &nnz, x, y);
mkl_cspblas_ccoosymv(&uplo, &m, val, rowind, colind, &nnz, x, y);
mkl_cspblas_zcoosymv(&uplo, &m, val, rowind, colind, &nnz, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_cspblas_?coosymv` routine performs a matrix-vector operation defined as

$$y := A*x$$

where:

x and y are vectors,

A is an upper or lower triangle of the symmetrical sparse matrix in the coordinate format with zero-based indexing.

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>val</i>	REAL for <code>mkl_cspblas_scoosymv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dcoosymv</code> . COMPLEX for <code>mkl_cspblas_ccoosymv</code> . DOUBLE COMPLEX for <code>mkl_cspblas_zcoosymv</code> . Array of length <i>nnz</i> , contains non-zero elements of the matrix A in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix A . Refer to <i>rows</i> array description in Coordinate Format for more details.

<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>x</i>	REAL for mkl_cspblas_scoosymv. DOUBLE PRECISION for mkl_cspblas_dcoosymv. COMPLEX for mkl_cspblas_ccoosymv. DOUBLE COMPLEX for mkl_cspblas_zcoosymv. Array, DIMENSION is <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> .

Output Parameters

<i>y</i>	REAL for mkl_cspblas_scoosymv. DOUBLE PRECISION for mkl_cspblas_dcoosymv. COMPLEX for mkl_cspblas_ccoosymv. DOUBLE COMPLEX for mkl_cspblas_zcoosymv. Array, DIMENSION at least <i>m</i> . On exit, the array <i>y</i> must contain the vector <i>y</i> .

```

mkl_cspblas_?csrtrsv

Triangular solvers with simplified interface for a sparse matrix in the CSR format (3-array variation) with zero-based indexing.

Syntax

Fortran:

```
call mkl_cspblas_scsrtrsv(uplo, transa, diag, m, a, ia, ja, x, y)
call mkl_cspblas_dcsrtrsv(uplo, transa, diag, m, a, ia, ja, x, y)
call mkl_cspblas_ccsrtrsv(uplo, transa, diag, m, a, ia, ja, x, y)
call mkl_cspblas_zcsrtrsv(uplo, transa, diag, m, a, ia, ja, x, y)
```

C:

```
mkl_cspblas_scsrtrsv(&uplo, &transa, &diag, &m, a, ia, ja, x, y);
mkl_cspblas_dcsrtrsv(&uplo, &transa, &diag, &m, a, ia, ja, x, y);
mkl_cspblas_ccsrtrsv(&uplo, &transa, &diag, &m, a, ia, ja, x, y);
mkl_cspblas_zcsrtrsv(&uplo, &transa, &diag, &m, a, ia, ja, x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_cspblas_?csrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the CSR format (3-array variation) with zero-based indexing:

$$A*y = x$$

or

$$A'*y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A'*y = x$,
<i>diag</i>	CHARACTER*1. Specifies whether matrix A is unit triangular. If <i>diag</i> = 'U' or 'u', then A is unit triangular. If <i>diag</i> = 'N' or 'n', then A is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>a</i>	REAL for <code>mkl_cspblas_scsrtrsv</code> . DOUBLE PRECISION for <code>mkl_cspblas_dcsrtrsv</code> . COMPLEX for <code>mkl_cspblas_ccsrtrsv</code> .

DOUBLE COMPLEX for `mkl_cspblas_zcsrtrsv`.
 Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

 **NOTE.** The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).
 No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

ia INTEGER. Array of length $m+1$, containing indices of elements in the array *a*, such that $ia(i)$ is the index in the array *a* of the first non-zero element from the row *i*. The value of the last element $ia(m)$ is equal to the number of non-zeros. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

ja INTEGER. Array containing the column indices for each non-zero element of the matrix A . Its length is equal to the length of the array *a*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

 **NOTE.** Column indices must be sorted in increasing order for each row.

x REAL for `mkl_cspblas_scsrtrsv`.
 DOUBLE PRECISION for `mkl_cspblas_dcsrtrsv`.
 COMPLEX for `mkl_cspblas_ccsrtrsv`.
 DOUBLE COMPLEX for `mkl_cspblas_zcsrtrsv`.
 Array, DIMENSION is *m*.
 On entry, the array *x* must contain the vector *x*.

Output Parameters

y REAL for mkl_cspblas_scsrtrsv.
 DOUBLE PRECISION for mkl_cspblas_dcsrtrsv.
 COMPLEX for mkl_cspblas_ccsrtrsv.
 DOUBLE COMPLEX for mkl_cspblas_zcsrtrsv.
 Array, DIMENSION at least m .
 Contains the vector y .

Interfaces

```

mkl_cspblas_?bsrtrsv

Triangular solver with simplified interface for a sparse matrix stored in the BSR format (3-array variation) with zero-based indexing.

Syntax**Fortran:**

```

call mkl_cspblas_sbsrtrsv(uplo, transa, diag, m, lb, a, ia, ja, x, y)
call mkl_cspblas_dbsrtrsv(uplo, transa, diag, m, lb, a, ia, ja, x, y)
call mkl_cspblas_cbsrtrsv(uplo, transa, diag, m, lb, a, ia, ja, x, y)
call mkl_cspblas_zbsrtrsv(uplo, transa, diag, m, lb, a, ia, ja, x, y)

```

C:

```

mkl_cspblas_sbsrtrsv(&uplo, &transa, &diag, &m, &lb, a, ia, ja, x, y);
mkl_cspblas_dbsrtrsv(&uplo, &transa, &diag, &m, &lb, a, ia, ja, x, y);
mkl_cspblas_cbsrtrsv(&uplo, &transa, &diag, &m, &lb, a, ia, ja, x, y);
mkl_cspblas_zbsrtrsv(&uplo, &transa, &diag, &m, &lb, a, ia, ja, x, y);

```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_cspblas_?bsrtrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the BSR format (3-array variation) with zero-based indexing:

$y := A*x$

or

$y := A'*x,$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies the upper or low triangle of the matrix A is used. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := A*x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := A'*x$.
<i>diag</i>	CHARACTER*1. Specifies whether matrix A is unit triangular or not. If <i>diag</i> = 'U' or 'u', A is unit triangular. If <i>diag</i> = 'N' or 'n', A is not unit triangular.
<i>m</i>	INTEGER. Number of block rows of the matrix A .
<i>lb</i>	INTEGER. Size of the block in the matrix A .

a REAL for `mkl_cspblas_sbsrtrmv`.
 DOUBLE PRECISION for `mkl_cspblas_dbsrtrmv`.
 COMPLEX for `mkl_cspblas_cbsrtrmv`.
 DOUBLE COMPLEX for `mkl_cspblas_zbsrtrmv`.
 Array containing elements of non-zero blocks of the matrix *A*. Its length is equal to the number of non-zero blocks in the matrix *A* multiplied by $lb*lb$. Refer to *values* array description in [BSR Format](#) for more details.

NOTE. The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

ia INTEGER. Array of length $(m + 1)$, containing indices of block in the array *a*, such that $ia(I)$ is the index in the array *a* of the first non-zero element from the row *I*. The value of the last element $ia(m + 1)$ is equal to the number of non-zero blocks. Refer to *rowIndex* array description in [BSR Format](#) for more details.

ja INTEGER. Array containing the column indices for each non-zero block in the matrix *A*. Its length is equal to the number of non-zero blocks of the matrix *A*. Refer to *columns* array description in [BSR Format](#) for more details.

x REAL for `mkl_cspblas_sbsrtrmv`.
 DOUBLE PRECISION for `mkl_cspblas_dbsrtrmv`.
 COMPLEX for `mkl_cspblas_cbsrtrmv`.
 DOUBLE COMPLEX for `mkl_cspblas_zbsrtrmv`.
 Array, DIMENSION $(m*lb)$.
 On entry, the array *x* must contain the vector *x*.

Output Parameters

y REAL for `mkl_cspblas_sbsrtrmv`.

DOUBLE PRECISION for mkl_cspblas_dbsrtrmv.
COMPLEX for mkl_cspblas_cbsrtrmv.
DOUBLE COMPLEX for mkl_cspblas_zbsrtrmv.
Array, DIMENSION at least $(m*lb)$.
On exit, the array y must contain the vector y .

```

mkl_cspblas_?cootrsv

Triangular solvers with simplified interface for a sparse matrix in the coordinate format with zero-based indexing .

Syntax**Fortran:**

```

call mkl_cspblas_scootrsv(uplo, transa, diag, m, val, rowind, colind, nnz,
x, y)
call mkl_cspblas_dcootrsv(uplo, transa, diag, m, val, rowind, colind, nnz,
x, y)
call mkl_cspblas_ccootrsv(uplo, transa, diag, m, val, rowind, colind, nnz,
x, y)
call mkl_cspblas_zcootrsv(uplo, transa, diag, m, val, rowind, colind, nnz,
x, y)

```

C:

```

mkl_cspblas_scootrsv(&uplo, &transa, &diag, &m, val, rowind, colind, &nnz,
x, y);
mkl_cspblas_dcootrsv(&uplo, &transa, &diag, &m, val, rowind, colind, &nnz,
x, y);

```

```
mkl_cspblass_ccootrsv(&uplo, &transa, &diag, &m, val, rowind, colind, &nnz,  
x, y);
```

```
mkl_cspblass_zcootrsv(&uplo, &transa, &diag, &m, val, rowind, colind, &nnz,  
x, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_cspblass_?cootrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the coordinate format with zero-based indexing:

$$A^*y = x$$

or

$$A^*y = x,$$

where:

x and y are vectors,

A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A^* is the transpose of A .

NOTE. This routine supports only zero-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>uplo</i>	CHARACTER*1. Specifies whether the upper or low triangle of the matrix A is considered. If <i>uplo</i> = 'U' or 'u', then the upper triangle of the matrix A is used. If <i>uplo</i> = 'L' or 'l', then the low triangle of the matrix A is used.
<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $A^*y = x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $A^*y = x,$

<i>diag</i>	CHARACTER*1. Specifies whether <i>A</i> is unit triangular. If <i>diag</i> = 'U' or 'u', then <i>A</i> is unit triangular. If <i>diag</i> = 'N' or 'n', then <i>A</i> is not unit triangular.
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .

```

mkl_?csr_mv

Computes matrix - vector product of a sparse matrix stored in the CSR format.

Syntax**Fortran:**

```

call mkl_scsrmv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x,
beta, y)
call mkl_dcrsrmv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x,
beta, y)
call mkl_ccrsrmv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x,
beta, y)
call mkl_zcrsrmv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x,
beta, y)

```

C:

```

mkl_scsrmv(&transa, &m, &k, &alpha, matdescra, val, indx, pntrb, pntre, x,
&beta, y);
mkl_dcrsrmv(&transa, &m, &k, &alpha, matdescra, val, indx, pntrb, pntre, x,
&beta, y);

```

```
mkl_ccsrmv(&transa, &m, &k, &alpha, matdescra, val, indx, pntreb, pntre, x,  
&beta, y);
```

```
mkl_zcsrmv(&transa, &m, &k, &alpha, matdescra, val, indx, pntreb, pntre, x,  
&beta, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?csrmv` routine performs a matrix-vector operation defined as

$$y := \alpha A x + \beta y$$

or

$$y := \alpha A' x + \beta y,$$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- k sparse matrix in the CSR format, A' is the transpose of A .

NOTE. This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha A x + \beta y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha A' x + \beta y$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>k</i>	INTEGER. Number of columns of the matrix A .
<i>alpha</i>	REAL for <code>mkl_scsrmv</code> . DOUBLE PRECISION for <code>mkl_dcsrmv</code> .

	<p>COMPLEX for <code>mkl_ccsrmv</code>. DOUBLE COMPLEX for <code>mkl_zcsrmv</code>. Specifies the scalar <i>alpha</i>.</p>
<i>matdescra</i>	<p>CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .</p>
<i>val</i>	<p>REAL for <code>mkl_scsrmv</code>. DOUBLE PRECISION for <code>mkl_dcsrmv</code>. COMPLEX for <code>mkl_ccsrmv</code>. DOUBLE COMPLEX for <code>mkl_zcsrmv</code>. Array containing non-zero elements of the matrix <i>A</i>. For one-based indexing its length is $pntrb(m) - pntrb(1)$. For zero-based indexing its length is $pntrb(m-1) - pntrb(0)$. Refer to <i>values</i> array description in CSR Format for more details.</p>
<i>indx</i>	<p>INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i>. Its length is equal to length of the <i>val</i> array. Refer to <i>columns</i> array description in CSR Format for more details.</p>
<i>pntrb</i>	<p>INTEGER. Array of length <i>m</i>. For one-based indexing this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i>. For zero-based indexing this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i>. Refer to <i>pointerb</i> array description in CSR Format for more details.</p>
<i>pntrc</i>	<p>INTEGER. Array of length <i>m</i>. For one-based indexing this array contains row indices, such that $pntrc(i) - pntrb(1)$ is the last index of row <i>i</i> in the arrays <i>val</i> and <i>indx</i>.</p>

For zero-based indexing this array contains row indices, such that $pntrb(i) - pntrb(0) - 1$ is the last index of row i in the arrays val and $indx$. Refer to *pointerE* array description in [CSR Format](#) for more details.

x	<p>REAL for <code>mkl_scsrvm</code>. DOUBLE PRECISION for <code>mkl_dcscrvm</code>. COMPLEX for <code>mkl_ccscrvm</code>. DOUBLE COMPLEX for <code>mkl_zcscrvm</code>. Array, DIMENSION at least k if $transa = 'N'$ or $'n'$ and at least m otherwise. On entry, the array x must contain the vector x.</p>
$beta$	<p>REAL for <code>mkl_scsrvm</code>. DOUBLE PRECISION for <code>mkl_dcscrvm</code>. COMPLEX for <code>mkl_ccscrvm</code>. DOUBLE COMPLEX for <code>mkl_zcscrvm</code>. Specifies the scalar $beta$.</p>
y	<p>REAL for <code>mkl_scsrvm</code>. DOUBLE PRECISION for <code>mkl_dcscrvm</code>. COMPLEX for <code>mkl_ccscrvm</code>. DOUBLE COMPLEX for <code>mkl_zcscrvm</code>. Array, DIMENSION at least m if $transa = 'N'$ or $'n'$ and at least k otherwise. On entry, the array y must contain the vector y.</p>

Output Parameters

y	Overwritten by the updated vector y .
-----	---

```

mkl_?bsrmv

Computes matrix - vector product of a sparse matrix stored in the BSR format.

Syntax

Fortran:

```
call mkl_sbsrmv(transa, m, k, lb, alpha, matdescra, val, indx, pntrb, pntre,
x, beta, y)
call mkl_dbsrmv(transa, m, k, lb, alpha, matdescra, val, indx, pntrb, pntre,
x, beta, y)
```

```
call mkl_cbsrmv(transa, m, k, lb, alpha, matdescra, val, indx, pntrb, pntre,
x, beta, y)
```

```
call mkl_zbsrmv(transa, m, k, lb, alpha, matdescra, val, indx, pntrb, pntre,
x, beta, y)
```

C:

```
mkl_sbsrmv(&transa, &m, &k, &lb, &alpha, matdescra, val, indx, pntrb, pntre,
x, &beta, y);
```

```
mkl_dbssrmv(&transa, &m, &k, &lb, &alpha, matdescra, val, indx, pntrb, pntre,
x, &beta, y);
```

```
mkl_cbsrmv(&transa, &m, &k, &lb, &alpha, matdescra, val, indx, pntrb, pntre,
x, &beta, y);
```

```
mkl_zbsrmv(&transa, &m, &k, &lb, &alpha, matdescra, val, indx, pntrb, pntre,
x, &beta, y);
```

Description

This routine is declared in `mkl_splblas.fi` for FORTRAN 77 interface and in `mkl_splblas.h` for C interface.

The `mkl_?bsrmv` routine performs a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y$$

or

$$y := \alpha * A' * x + \beta * y,$$

where:

alpha and *beta* are scalars,

x and *y* are vectors,

A is an *m*-by-*k* block sparse matrix in the BSR format, *A'* is the transpose of *A*.

NOTE. This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section **“Interfaces”** below.

<i>transa</i>	<p>CHARACTER*1. Specifies the operation.</p> <p>If <i>transa</i> = 'N' or 'n', then the matrix-vector product is computed as $y := \alpha * A * x + \beta * y$</p> <p>If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $y := \alpha * A' * x + \beta * y$,</p>
<i>m</i>	INTEGER. Number of block rows of the matrix <i>A</i> .
<i>k</i>	INTEGER. Number of block columns of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>alpha</i>	<p>REAL for mkl_sbsrmv.</p> <p>DOUBLE PRECISION for mkl_dbsrmv.</p> <p>COMPLEX for mkl_cbsrmv.</p> <p>DOUBLE COMPLEX for mkl_zbsrmv.</p> <p>Specifies the scalar <i>alpha</i>.</p>
<i>matdescra</i>	<p>CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 .</p> <p>Possible combinations of element values of this parameter are given in Table 2-7 .</p>
<i>val</i>	<p>REAL for mkl_sbsrmv.</p> <p>DOUBLE PRECISION for mkl_dbsrmv.</p> <p>COMPLEX for mkl_cbsrmv.</p> <p>DOUBLE COMPLEX for mkl_zbsrmv.</p> <p>Array containing elements of non-zero blocks of the matrix <i>A</i>. Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by $lb * lb$.</p> <p>Refer to <i>values</i> array description in BSR Format for more details.</p>
<i>indx</i>	<p>INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i>. Its length is equal to the number of non-zero blocks in the matrix <i>A</i>.</p>

	Refer to <i>columns</i> array description in BSR Format for more details.
<i>pntrb</i>	<p>INTEGER. Array of length <i>m</i>.</p> <p>For one-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of block row <i>i</i> in the array <i>indx</i>.</p> <p>For zero-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of block row <i>i</i> in the array <i>indx</i>.</p> <p>Refer to <i>pointerB</i> array description in BSR Format for more details.</p>
<i>pntrr</i>	<p>INTEGER. Array of length <i>m</i>.</p> <p>For one-based indexing this array contains row indices, such that $pntrr(i) - pntrb(1)$ is the last index of block row <i>i</i> in the array <i>indx</i>.</p> <p>For zero-based indexing this array contains row indices, such that $pntrr(i) - pntrb(0) - 1$ is the last index of block row <i>i</i> in the array <i>indx</i>.</p> <p>Refer to <i>pointerE</i> array description in BSR Format for more details.</p>
<i>x</i>	<p>REAL for <code>mkl_sbsrmv</code>.</p> <p>DOUBLE PRECISION for <code>mkl_dbsrmv</code>.</p> <p>COMPLEX for <code>mkl_cbsrmv</code>.</p> <p>DOUBLE COMPLEX for <code>mkl_zbsrmv</code>.</p> <p>Array, DIMENSION at least $(k \cdot lb)$ if <i>transa</i> = 'N' or 'n', and at least $(m \cdot lb)$ otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i>.</p>
<i>beta</i>	<p>REAL for <code>mkl_sbsrmv</code>.</p> <p>DOUBLE PRECISION for <code>mkl_dbsrmv</code>.</p> <p>COMPLEX for <code>mkl_cbsrmv</code>.</p> <p>DOUBLE COMPLEX for <code>mkl_zbsrmv</code>.</p> <p>Specifies the scalar <i>beta</i>.</p>
<i>y</i>	<p>REAL for <code>mkl_sbsrmv</code>.</p> <p>DOUBLE PRECISION for <code>mkl_dbsrmv</code>.</p> <p>COMPLEX for <code>mkl_cbsrmv</code>.</p> <p>DOUBLE COMPLEX for <code>mkl_zbsrmv</code>.</p>

Array, DIMENSION at least $(m*lb)$ if $transa = 'N'$ or $'n'$, and at least $(k*lb)$ otherwise. On entry, the array y must contain the vector y .

Output Parameters

y Overwritten by the updated vector y .

Interfaces

```

mkl_?cscmv

Computes matrix-vector product for a sparse matrix in the CSC format.

Syntax

Fortran:

```
call mkl_scscmv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x,  
beta, y)
```

```
call mkl_dcscmv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x,  
beta, y)
```

```
call mkl_ccscmv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x,  
beta, y)
```

```
call mkl_zcscmv(transa, m, k, alpha, matdescra, val, indx, pntrb, pntre, x,  
beta, y)
```

C:

```
mkl_scscmv(&transa, &m, &k, &alpha, matdescra, val, indx, pntrb, pntre, x,  
&beta, y);
```

```
mkl_dcscmv(&transa, &m, &k, &alpha, matdescra, val, indx, pntrb, pntre, x,  
&beta, y);
```

```
mkl_ccscmv(&transa, &m, &k, &alpha, matdescra, val, indx, pntrb, pntre, x,  
&beta, y);
```

```
mkl_zcscmv(&transa, &m, &k, &alpha, matdescra, val, indx, pntrb, pntre, x,  
&beta, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?cscmv` routine performs a matrix-vector operation defined as

```
 $y := \alpha A x + \beta y$ 
```

or

```
 $y := \alpha A' x + \beta y,$ 
```

where:

α and β are scalars,

x and y are vectors,

A is an m -by- k sparse matrix in compressed sparse column (CSC) format, A' is the transpose of A .

NOTE. This routine supports CSC format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha A x + \beta y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha A' x + \beta y$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>k</i>	INTEGER. Number of columns of the matrix A .
<i>alpha</i>	REAL for mkl_scscmv. DOUBLE PRECISION for mkl_dcscmv. COMPLEX for mkl_ccscmv. DOUBLE COMPLEX for mkl_zcscmv. Specifies the scalar α .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .
<i>val</i>	REAL for mkl_scscmv. DOUBLE PRECISION for mkl_dcscmv. COMPLEX for mkl_ccscmv. DOUBLE COMPLEX for mkl_zcscmv. Array containing non-zero elements of the matrix A .

	<p>For one-based indexing its length is $\text{pntrb}(k) - \text{pntrb}(1)$. For zero-based indexing its length is $\text{pntrb}(m-1) - \text{pntrb}(0)$. Refer to <i>values</i> array description in CSC Format for more details.</p>
<i>indx</i>	<p>INTEGER. Array containing the row indices for each non-zero element of the matrix <i>A</i>. Its length is equal to length of the <i>val</i> array. Refer to <i>rows</i> array description in CSC Format for more details.</p>
<i>pntrb</i>	<p>INTEGER. Array of length <i>k</i>. For one-based indexing this array contains column indices, such that $\text{pntrb}(i) - \text{pntrb}(1) + 1$ is the first index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i>. For zero-based indexing this array contains column indices, such that $\text{pntrb}(i) - \text{pntrb}(0)$ is the first index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i>. Refer to <i>pointerb</i> array description in CSC Format for more details.</p>
<i>pntrb</i>	<p>INTEGER. Array of length <i>k</i>. For one-based indexing this array contains column indices, such that $\text{pntrb}(i) - \text{pntrb}(1)$ is the last index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i>. For zero-based indexing this array contains column indices, such that $\text{pntrb}(i) - \text{pntrb}(1) - 1$ is the last index of column <i>i</i> in the arrays <i>val</i> and <i>indx</i>. Refer to <i>pointerE</i> array description in CSC Format for more details.</p>
<i>x</i>	<p>REAL for mkl_scscmv. DOUBLE PRECISION for mkl_dcscmv. COMPLEX for mkl_ccscmv. DOUBLE COMPLEX for mkl_zcscmv. Array, DIMENSION at least <i>k</i> if <i>transa</i> = 'N' or 'n' and at least <i>m</i> otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i>.</p>
<i>beta</i>	<p>REAL for mkl_scscmv. DOUBLE PRECISION for mkl_dcscmv. COMPLEX for mkl_ccscmv.</p>

y DOUBLE COMPLEX for mkl_zcscmv.
Specifies the scalar β .

y REAL for mkl_scscmv.
DOUBLE PRECISION for mkl_dcscmv.
COMPLEX for mkl_ccscmv.
DOUBLE COMPLEX for mkl_zcscmv.
Array, DIMENSION at least m if $transa = 'N'$ or $'n'$ and at least k otherwise. On entry, the array y must contain the vector y .

Output Parameters

y Overwritten by the updated vector y .

Interfaces

```

mkl_?coomv

Computes matrix - vector product for a sparse matrix in the coordinate format.

Syntax

Fortran:

```
call mkl_scoomv(transa, m, k, alpha, matdescra, val, rowind, colind, nnz, x,
beta, y)
```

```
call mkl_dcoomv(transa, m, k, alpha, matdescra, val, rowind, colind, nnz, x,  
beta, y)
```

```
call mkl_ccoomv(transa, m, k, alpha, matdescra, val, rowind, colind, nnz, x,  
beta, y)
```

```
call mkl_zcoomv(transa, m, k, alpha, matdescra, val, rowind, colind, nnz, x,  
beta, y)
```

C:

```
mkl_scoomv(&transa, &m, &k, &alpha, matdescra, val, rowind, colind, &nnz, x,  
&beta, y);
```

```
mkl_dcoomv(&transa, &m, &k, &alpha, matdescra, val, rowind, colind, &nnz, x,  
&beta, y);
```

```
mkl_ccoomv(&transa, &m, &k, &alpha, matdescra, val, rowind, colind, &nnz, x,  
&beta, y);
```

```
mkl_zcoomv(&transa, &m, &k, &alpha, matdescra, val, rowind, colind, &nnz, x,  
&beta, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?coomv` routine performs a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y$$

or

$$y := \alpha * A' * x + \beta * y,$$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- k sparse matrix in compressed coordinate format, A' is the transpose of A .

NOTE. This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	<p>CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha * A * x + \beta * y$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * A' * x + \beta * y$,</p>
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	<p>REAL for <code>mkl_scoomv</code>. DOUBLE PRECISION for <code>mkl_dcoomv</code>. COMPLEX for <code>mkl_ccoomv</code>. DOUBLE COMPLEX for <code>mkl_zcoomv</code>. Specifies the scalar <i>alpha</i>.</p>
<i>matdescra</i>	<p>CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .</p>
<i>val</i>	<p>REAL for <code>mkl_scoomv</code>. DOUBLE PRECISION for <code>mkl_dcoomv</code>. COMPLEX for <code>mkl_ccoomv</code>. DOUBLE COMPLEX for <code>mkl_zcoomv</code>. Array of length <i>nnz</i>, contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.</p>
<i>rowind</i>	<p>INTEGER. Array of length <i>nnz</i>, contains the row indices for each non-zero element of the matrix <i>A</i>. Refer to <i>rows</i> array description in Coordinate Format for more details.</p>
<i>colind</i>	<p>INTEGER. Array of length <i>nnz</i>, contains the column indices for each non-zero element of the matrix <i>A</i>. Refer to <i>columns</i> array description in Coordinate Format for more details.</p>

<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>x</i>	REAL for <code>mkl_scoomv</code> . DOUBLE PRECISION for <code>mkl_dcoomv</code> . COMPLEX for <code>mkl_ccoomv</code> . DOUBLE COMPLEX for <code>mkl_zcoomv</code> . Array, DIMENSION at least <i>k</i> if <i>transa</i> = 'N' or 'n' and at least <i>m</i> otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i> .
<i>beta</i>	REAL for <code>mkl_scoomv</code> . DOUBLE PRECISION for <code>mkl_dcoomv</code> . COMPLEX for <code>mkl_ccoomv</code> . DOUBLE COMPLEX for <code>mkl_zcoomv</code> . Specifies the scalar <i>beta</i> .
<i>y</i>	REAL for <code>mkl_scoomv</code> . DOUBLE PRECISION for <code>mkl_dcoomv</code> . COMPLEX for <code>mkl_ccoomv</code> . DOUBLE COMPLEX for <code>mkl_zcoomv</code> . Array, DIMENSION at least <i>m</i> if <i>transa</i> = 'N' or 'n' and at least <i>k</i> otherwise. On entry, the array <i>y</i> must contain the vector <i>y</i> .

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .
----------	--

```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?csrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the CSR format:

$$y := \alpha \cdot \text{inv}(A) \cdot x$$

or

$$y := \alpha \cdot \text{inv}(A') \cdot x,$$

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section **“Interfaces”** below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $y := \alpha \cdot \text{inv}(A) \cdot x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha \cdot \text{inv}(A') \cdot x$,
<i>m</i>	INTEGER. Number of columns of the matrix A .
<i>alpha</i>	REAL for <code>mkl_scsrsv</code> . DOUBLE PRECISION for <code>mkl_dcsrsv</code> . COMPLEX for <code>mkl_ccsrsv</code> . DOUBLE COMPLEX for <code>mkl_zcsrsv</code> . Specifies the scalar α .

matdescra CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in [Table 2-6](#) . Possible combinations of element values of this parameter are given in [Table 2-7](#) .

val REAL for `mkl_scsrsv`.
 DOUBLE PRECISION for `mkl_dcsrsv`.
 COMPLEX for `mkl_ccsrsv`.
 DOUBLE COMPLEX for `mkl_zcsrsv`.
 Array containing non-zero elements of the matrix *A*.
 For one-based indexing its length is $pntrb(m) - pntrb(1)$.
 For zero-based indexing its length is $pntrb(m-1) - pntrb(0)$.
 Refer to *values* array description in [CSR Format](#) for more details.

NOTE. The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

indx INTEGER. Array containing the column indices for each non-zero element of the matrix *A*. Its length is equal to length of the *val* array.
 Refer to *columns* array description in [CSR Format](#) for more details.

NOTE. Column indices must be sorted in increasing order for each row.

pntrb INTEGER. Array of length *m*.
 For one-based indexing this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of row *i* in the arrays *val* and *indx*.

	For zero-based indexing this array contains row indices, such that $pntreb(i) - pntreb(0)$ is the first index of row i in the arrays val and $indx$. Refer to <i>pointerb</i> array description in CSR Format for more details.
<i>pntre</i>	<p>INTEGER. Array of length m.</p> <p>For one-based indexing this array contains row indices, such that $pntre(i) - pntreb(1)$ is the last index of row i in the arrays val and $indx$.</p> <p>For zero-based indexing this array contains row indices, such that $pntre(i) - pntreb(0) - 1$ is the last index of row i in the arrays val and $indx$. Refer to <i>pointerE</i> array description in CSR Format for more details.</p>
<i>x</i>	<p>REAL for mkl_scsrsv.</p> <p>DOUBLE PRECISION for mkl_dcsrsv.</p> <p>COMPLEX for mkl_ccsrsv.</p> <p>DOUBLE COMPLEX for mkl_zcsrsv.</p> <p>Array, DIMENSION at least m.</p> <p>On entry, the array x must contain the vector x. The elements are accessed with unit increment.</p>
<i>y</i>	<p>REAL for mkl_scsrsv.</p> <p>DOUBLE PRECISION for mkl_dcsrsv.</p> <p>COMPLEX for mkl_ccsrsv.</p> <p>DOUBLE COMPLEX for mkl_zcsrsv.</p> <p>Array, DIMENSION at least m.</p> <p>On entry, the array y must contain the vector y. The elements are accessed with unit increment.</p>

Output Parameters

<i>y</i>	Contains solution vector x .

y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?bsrsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the BSR format:

$$y := \alpha \text{inv}(A) * x$$

or

$$y := \alpha \text{inv}(A') * x,$$

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

transa CHARACTER*1. Specifies the operation.

	<p>If <i>transa</i> = 'N' or 'n', then $y := \alpha * \text{inv}(A) * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * \text{inv}(A') * x$,</p>
<i>m</i>	INTEGER. Number of block columns of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>alpha</i>	<p>REAL for <code>mkl_sbsrsv</code>. DOUBLE PRECISION for <code>mkl_dbsrsv</code>. COMPLEX for <code>mkl_cbsrsv</code>. DOUBLE COMPLEX for <code>mkl_zbsrsv</code>. Specifies the scalar <i>alpha</i>.</p>
<i>matdescra</i>	<p>CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .</p>
<i>val</i>	<p>REAL for <code>mkl_sbsrsv</code>. DOUBLE PRECISION for <code>mkl_dbsrsv</code>. COMPLEX for <code>mkl_cbsrsv</code>. DOUBLE COMPLEX for <code>mkl_zbsrsv</code>. Array containing elements of non-zero blocks of the matrix <i>A</i>. Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb*lb</i>. Refer to the <i>values</i> array description in BSR Format for more details.</p>
	<hr/> <p> NOTE. The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).</p> <p>No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.</p> <hr/>
<i>indx</i>	<p>INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i>. Its length is equal to the number of non-zero blocks in the matrix <i>A</i>.</p>

<i>pntrb</i>	<p>Refer to the <i>columns</i> array description in BSR Format for more details.</p> <p>INTEGER. Array of length <i>m</i>.</p> <p>For one-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of block row <i>i</i> in the array <i>indx</i>.</p> <p>For zero-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of block row <i>i</i> in the array <i>indx</i>.</p> <p>Refer to <i>pointerB</i> array description in BSR Format for more details.</p>
<i>pntrc</i>	<p>INTEGER. Array of length <i>m</i>.</p> <p>For one-based indexing this array contains row indices, such that $pntrc(i) - pntrb(1)$ is the last index of block row <i>i</i> in the array <i>indx</i>.</p> <p>For zero-based indexing this array contains row indices, such that $pntrc(i) - pntrb(0) - 1$ is the last index of block row <i>i</i> in the array <i>indx</i>.</p> <p>Refer to <i>pointerE</i> array description in BSR Format for more details.</p>
<i>x</i>	<p>REAL for mkl_sbsrsv.</p> <p>DOUBLE PRECISION for mkl_dbsrsv.</p> <p>COMPLEX for mkl_cbsrsv.</p> <p>DOUBLE COMPLEX for mkl_zbsrsv.</p> <p>Array, DIMENSION at least ($m * lb$).</p> <p>On entry, the array <i>x</i> must contain the vector <i>x</i>. The elements are accessed with unit increment.</p>
<i>y</i>	<p>REAL for mkl_sbsrsv.</p> <p>DOUBLE PRECISION for mkl_dbsrsv.</p> <p>COMPLEX for mkl_cbsrsv.</p> <p>DOUBLE COMPLEX for mkl_zbsrsv.</p> <p>Array, DIMENSION at least ($m * lb$).</p> <p>On entry, the array <i>y</i> must contain the vector <i>y</i>. The elements are accessed with unit increment.</p>

Output Parameters

<i>y</i>	Contains solution vector <i>x</i> .

```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?cscsv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the CSC format:

$$y := \alpha * \text{inv}(A) * x$$

or

$$y := \alpha * \text{inv}(A') * x,$$

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports a CSC format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section **"Interfaces"** below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $y := \alpha * \text{inv}(A) * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * \text{inv}(A') * x$,
<i>m</i>	INTEGER. Number of columns of the matrix A .

<i>alpha</i>	<p>REAL for <code>mkl_scscsv</code>. DOUBLE PRECISION for <code>mkl_dcscsv</code>. COMPLEX for <code>mkl_ccscsv</code>. DOUBLE COMPLEX for <code>mkl_zcscsv</code>. Specifies the scalar <i>alpha</i>.</p>
<i>matdescra</i>	<p>CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .</p>
<i>val</i>	<p>REAL for <code>mkl_scscsv</code>. DOUBLE PRECISION for <code>mkl_dcscsv</code>. COMPLEX for <code>mkl_ccscsv</code>. DOUBLE COMPLEX for <code>mkl_zcscsv</code>. Array containing non-zero elements of the matrix <i>A</i>. For one-based indexing its length is $pntre(m) - pntrb(1)$. For zero-based indexing its length is $pntre(m-1) - pntrb(0)$. Refer to <i>values</i> array description in CSC Format for more details.</p>

NOTE. The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

<i>indx</i>	<p>INTEGER. Array containing the row indices for each non-zero element of the matrix <i>A</i>. Its length is equal to length of the <i>val</i> array. Refer to <i>columns</i> array description in CSC Format for more details.</p>
-------------	--

NOTE. Row indices must be sorted in increasing order for each column.

<i>pntrb</i>	<p>INTEGER. Array of length m.</p> <p>For one-based indexing this array contains column indices, such that $pntrb(i) - pntrb(1)+1$ is the first index of column i in the arrays <i>val</i> and <i>indx</i>.</p> <p>For zero-based indexing this array contains column indices, such that $pntrb(i) - pntrb(0)$ is the first index of column i in the arrays <i>val</i> and <i>indx</i>.</p> <p>Refer to <i>pointerb</i> array description in CSC Format for more details.</p>
<i>pntrc</i>	<p>INTEGER. Array of length m.</p> <p>For one-based indexing this array contains column indices, such that $pntrc(i) - pntrb(1)$ is the last index of column i in the arrays <i>val</i> and <i>indx</i>.</p> <p>For zero-based indexing this array contains column indices, such that $pntrc(i) - pntrb(1)-1$ is the last index of column i in the arrays <i>val</i> and <i>indx</i>.</p> <p>Refer to <i>pointerE</i> array description in CSC Format for more details.</p>
<i>x</i>	<p>REAL for mkl_scscsv. DOUBLE PRECISION for mkl_dcscsv. COMPLEX for mkl_ccscsv. DOUBLE COMPLEX for mkl_zcscsv.</p> <p>Array, DIMENSION at least m.</p> <p>On entry, the array <i>x</i> must contain the vector x. The elements are accessed with unit increment.</p>
<i>y</i>	<p>REAL for mkl_scscsv. DOUBLE PRECISION for mkl_dcscsv. COMPLEX for mkl_ccscsv. DOUBLE COMPLEX for mkl_zcscsv.</p> <p>Array, DIMENSION at least m.</p> <p>On entry, the array <i>y</i> must contain the vector y. The elements are accessed with unit increment.</p>

Output Parameters

<i>y</i>	Contains the solution vector x .

```

mkl_?coosv

Solves a system of linear equations for a sparse matrix in the coordinate format.

Syntax

Fortran:

```
call mkl_scoosv(transa, m, k, alpha, matdescra, val, rowind, colind, nnz, x,
y)
call mkl_dcoosv(transa, m, k, alpha, matdescra, val, rowind, colind, nnz, x,
y)
call mkl_ccoosv(transa, m, k, alpha, matdescra, val, rowind, colind, nnz, x,
y)
```

```
call mkl_zcoosv(transa, m, k, alpha, matdescra, val, rowind, colind, nnz, x,
y)
```

C:

```
mkl_scoosv(&transa, &m, &k, &alpha, matdescra, val, rowind, colind, &nnz, x,
y);
```

```
mkl_dcoosv(&transa, &m, &k, &alpha, matdescra, val, rowind, colind, &nnz, x,
y);
```

```
mkl_ccoosv(&transa, &m, &k, &alpha, matdescra, val, rowind, colind, &nnz, x,
y);
```

```
mkl_zcoosv(&transa, &m, &k, &alpha, matdescra, val, rowind, colind, &nnz, x,
y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?coosv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the coordinate format:

$$y := \alpha * \text{inv}(A) * x$$

or

$$y := \alpha * \text{inv}(A') * x,$$

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

transa CHARACTER*1. Specifies the system of linear equations.

	<p>If <i>transa</i> = 'N' or 'n', then $y := \alpha * \text{inv}(A) * x$</p> <p>If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * \text{inv}(A') * x$,</p>
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>alpha</i>	<p>REAL for mkl_scoosv.</p> <p>DOUBLE PRECISION for mkl_dcoosv.</p> <p>COMPLEX for mkl_ccoosv.</p> <p>DOUBLE COMPLEX for mkl_zcoosv.</p> <p>Specifies the scalar <i>alpha</i>.</p>
<i>matdescra</i>	<p>CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .</p>
<i>val</i>	<p>REAL for mkl_scoosv.</p> <p>DOUBLE PRECISION for mkl_dcoosv.</p> <p>COMPLEX for mkl_ccoosv.</p> <p>DOUBLE COMPLEX for mkl_zcoosv.</p> <p>Array of length <i>nnz</i>, contains non-zero elements of the matrix <i>A</i> in the arbitrary order.</p> <p>Refer to <i>values</i> array description in Coordinate Format for more details.</p>
<i>rowind</i>	<p>INTEGER. Array of length <i>nnz</i>, contains the row indices for each non-zero element of the matrix <i>A</i>.</p> <p>Refer to <i>rows</i> array description in Coordinate Format for more details.</p>
<i>colind</i>	<p>INTEGER. Array of length <i>nnz</i>, contains the column indices for each non-zero element of the matrix <i>A</i>. Refer to <i>columns</i> array description in Coordinate Format for more details.</p>
<i>nnz</i>	<p>INTEGER. Specifies the number of non-zero element of the matrix <i>A</i>.</p> <p>Refer to <i>nnz</i> description in Coordinate Format for more details.</p>
<i>x</i>	<p>REAL for mkl_scoosv.</p> <p>DOUBLE PRECISION for mkl_dcoosv.</p> <p>COMPLEX for mkl_ccoosv.</p> <p>DOUBLE COMPLEX for mkl_zcoosv.</p>

y Array, DIMENSION at least m .
On entry, the array x must contain the vector x . The elements are accessed with unit increment.

y REAL for mkl_scoosv.
DOUBLE PRECISION for mkl_dcoosv.
COMPLEX for mkl_ccoosv.
DOUBLE COMPLEX for mkl_zcoosv.
Array, DIMENSION at least m .
On entry, the array y must contain the vector y . The elements are accessed with unit increment.

Output Parameters

y Contains solution vector x .

b, &ldb, &beta, c, &ldc);
```

```
mkl_zcsrmm(&transa, &m, &n, &k, &alpha, matdescra, val, indx, pntreb, pntre,  
b, &ldb, &beta, c, &ldc);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?csrmm` routine performs a matrix-matrix operation defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * A' * B + \beta * C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in compressed sparse row (CSR) format, *A'* is the transpose of *A*.

NOTE. This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	<p>CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * A' * B + \beta * C$,</p>
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	<p>REAL for mkl_scsrmm. DOUBLE PRECISION for mkl_dcsrmm. COMPLEX for mkl_ccsrmm. DOUBLE COMPLEX for mkl_zcsrmm. Specifies the scalar <i>alpha</i>.</p>
<i>matdescra</i>	<p>CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .</p>
<i>val</i>	<p>REAL for mkl_scsrmm. DOUBLE PRECISION for mkl_dcsrmm. COMPLEX for mkl_ccsrmm. DOUBLE COMPLEX for mkl_zcsrmm. Array containing non-zero elements of the matrix <i>A</i>. For one-based indexing its length is $pntre(m) - pntrb(1)$. For zero-based indexing its length is $pntre(-1) - pntrb(0)$. Refer to <i>values</i> array description in CSR Format for more details.</p>
<i>indx</i>	<p>INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i>. Its length is equal to length of the <i>val</i> array. Refer to <i>columns</i> array description in CSR Format for more details.</p>

<i>pntrb</i>	<p>INTEGER. Array of length m.</p> <p>For one-based indexing this array contains row indices, such that $pntrb(I) - pntrb(1)+1$ is the first index of row I in the arrays <i>val</i> and <i>indx</i>.</p> <p>For zero-based indexing this array contains row indices, such that $pntrb(I) - pntrb(0)$ is the first index of row I in the arrays <i>val</i> and <i>indx</i>.</p> <p>Refer to <i>pointerb</i> array description in CSR Format for more details.</p>
<i>pntrE</i>	<p>INTEGER. Array of length m.</p> <p>For one-based indexing this array contains row indices, such that $pntrE(I) - pntrb(1)$ is the last index of row I in the arrays <i>val</i> and <i>indx</i>.</p> <p>For zero-based indexing this array contains row indices, such that $pntrE(I) - pntrb(0)-1$ is the last index of row I in the arrays <i>val</i> and <i>indx</i>.</p> <p>Refer to <i>pointerE</i> array description in CSR Format for more details.</p>
<i>b</i>	<p>REAL for <code>mkl_scsrmm</code>.</p> <p>DOUBLE PRECISION for <code>mkl_dcsrmm</code>.</p> <p>COMPLEX for <code>mkl_ccsrmm</code>.</p> <p>DOUBLE COMPLEX for <code>mkl_zcsrmm</code>.</p> <p>Array, DIMENSION (<i>ldb</i>, at least n for non-transposed matrix A and at least m for transposed) for one-based indexing, and (at least k for non-transposed matrix A and at least m for transposed, <i>ldb</i>) for zero-based indexing.</p> <p>On entry with <i>transa</i>= 'N' or 'n', the leading k-by-n part of the array <i>b</i> must contain the matrix B, otherwise the leading m-by-n part of the array <i>b</i> must contain the matrix B.</p>
<i>ldb</i>	<p>INTEGER. Specifies the first dimension of <i>b</i> for one-based indexing, and the second dimension of <i>b</i> for zero-based indexing, as declared in the calling (sub)program.</p>
<i>beta</i>	<p>REAL for <code>mkl_scsrmm</code>.</p> <p>DOUBLE PRECISION for <code>mkl_dcsrmm</code>.</p> <p>COMPLEX for <code>mkl_ccsrmm</code>.</p> <p>DOUBLE COMPLEX for <code>mkl_zcsrmm</code>.</p> <p>Specifies the scalar <i>beta</i>.</p>

c REAL for mkl_scsrmm.
DOUBLE PRECISION for mkl_dcsrmm.
COMPLEX for mkl_ccsrmm.
DOUBLE COMPLEX for mkl_zcsrmm.
Array, DIMENSION (*ldc*, *n*) for one-based indexing, and (*m*, *ldc*) for zero-based indexing.
On entry, the leading *m*-by-*n* part of the array *c* must contain the matrix *C*, otherwise the leading *k*-by-*n* part of the array *c* must contain the matrix *C*.

ldc INTEGER. Specifies the first dimension of *c* for one-based indexing, and the second dimension of *c* for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c Overwritten by the matrix ($\alpha * A * B + \beta * C$) or ($\alpha * A' * B + \beta * C$).

```

```
mkl_cbsrmm(&transa, &m, &n, &k, &lb, &alpha, matdescra, val, indx, pntrb,  
pntre, b, &ldb, &beta, c, &ldc);
```

```
mkl_zbsrmm(&transa, &m, &n, &k, &lb, &alpha, matdescra, val, indx, pntrb,  
pntre, b, &ldb, &beta, c, &ldc);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?bsrmm` routine performs a matrix-matrix operation defined as

$$C := \alpha A * B + \beta C$$

or

$$C := \alpha A' * B + \beta C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in block sparse row (BSR) format, *A'* is the transpose of *A*.

NOTE. This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section **“Interfaces”** below.

<i>transa</i>	<p>CHARACTER*1. Specifies the operation.</p> <p>If <i>transa</i> = 'N' or 'n', then the matrix-matrix product is computed as $C := \alpha * A * B + \beta * C$</p> <p>If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $C := \alpha * A' * B + \beta * C$,</p>
<i>m</i>	INTEGER. Number of block rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of block columns of the matrix <i>A</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>alpha</i>	<p>REAL for mkl_sbsrmm.</p> <p>DOUBLE PRECISION for mkl_dbsrmm.</p> <p>COMPLEX for mkl_cbsrmm.</p> <p>DOUBLE COMPLEX for mkl_zbsrmm.</p> <p>Specifies the scalar <i>alpha</i>.</p>
<i>matdescra</i>	<p>CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 .</p> <p>Possible combinations of element values of this parameter are given in Table 2-7 .</p>
<i>val</i>	<p>REAL for mkl_sbsrmm.</p> <p>DOUBLE PRECISION for mkl_dbsrmm.</p> <p>COMPLEX for mkl_cbsrmm.</p> <p>DOUBLE COMPLEX for mkl_zbsrmm.</p> <p>Array containing elements of non-zero blocks of the matrix <i>A</i>. Its length is equal to the number of non-zero blocks in the matrix <i>A</i> multiplied by $lb * lb$. Refer to the <i>values</i> array description in BSR Format for more details.</p>
<i>indx</i>	<p>INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i>. Its length is equal to the number of non-zero blocks in the matrix <i>A</i>. Refer to the <i>columns</i> array description in BSR Format for more details.</p>

<i>pntrb</i>	<p>INTEGER. Array of length m.</p> <p>For one-based indexing: this array contains row indices, such that $pntrb(I) - pntrb(1)+1$ is the first index of block row I in the array <i>indx</i>.</p> <p>For zero-based indexing: this array contains row indices, such that $pntrb(I) - pntrb(0)$ is the first index of block row I in the array <i>indx</i>.</p> <p>Refer to <i>pointerB</i> array description in BSR Format for more details.</p>
<i>pntrc</i>	<p>INTEGER. Array of length m.</p> <p>For one-based indexing this array contains row indices, such that $pntrc(I) - pntrb(1)$ is the last index of block row I in the array <i>indx</i>.</p> <p>For zero-based indexing this array contains row indices, such that $pntrc(I) - pntrb(0)-1$ is the last index of block row I in the array <i>indx</i>.</p> <p>Refer to <i>pointerE</i> array description in BSR Format for more details.</p>
<i>b</i>	<p>REAL for mkl_sbsrmm. DOUBLE PRECISION for mkl_dbsrmm. COMPLEX for mkl_cbsrmm. DOUBLE COMPLEX for mkl_zbsrmm.</p> <p>Array, DIMENSION (<i>ldb</i>, at least n for non-transposed matrix A and at least m for transposed) for one-based indexing, and (at least k for non-transposed matrix A and at least m for transposed, <i>ldb</i>) for zero-based indexing.</p> <p>On entry with <i>transa</i>= 'N' or 'n', the leading n-by-k block part of the array <i>b</i> must contain the matrix B, otherwise the leading m-by-n block part of the array <i>b</i> must contain the matrix B.</p>
<i>ldb</i>	<p>INTEGER. Specifies the first dimension (in blocks) of <i>b</i> as declared in the calling (sub)program.</p>
<i>beta</i>	<p>REAL for mkl_sbsrmm. DOUBLE PRECISION for mkl_dbsrmm. COMPLEX for mkl_cbsrmm. DOUBLE COMPLEX for mkl_zbsrmm.</p> <p>Specifies the scalar <i>beta</i>.</p>
<i>c</i>	<p>REAL for mkl_sbsrmm.</p>

DOUBLE PRECISION for `mkl_dbsrmm`.
COMPLEX for `mkl_cbsrmm`.
DOUBLE COMPLEX for `mkl_zbsrmm`.
Array, DIMENSION (ldc , n) for one-based indexing,
DIMENSION (k , ldc) for zero-based indexing.
On entry, the leading m -by- n block part of the array c must
contain the matrix C , otherwise the leading n -by- k block
part of the array c must contain the matrix C .
 ldc INTEGER. Specifies the first dimension (in blocks) of c as
declared in the calling (sub)program.

Output Parameters

c Overwritten by the matrix $(\alpha * A * B + \beta * C)$ or
 $(\alpha * A' * B + \beta * C)$.

Interfaces

```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?cscmm` routine performs a matrix-matrix operation defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * A' * B + \beta * C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in compressed sparse column (CSC) format, *A'* is the transpose of *A*.

NOTE. This routine supports CSC format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	<p>CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * A' * B + \beta * C$,</p>
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	<p>REAL for mkl_scscmm. DOUBLE PRECISION for mkl_dcscmm. COMPLEX for mkl_ccscmm. DOUBLE COMPLEX for mkl_zcscmm. Specifies the scalar <i>alpha</i>.</p>
<i>matdescra</i>	<p>CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .</p>
<i>val</i>	<p>REAL for mkl_scscmm. DOUBLE PRECISION for mkl_dcscmm. COMPLEX for mkl_ccscmm. DOUBLE COMPLEX for mkl_zcscmm. Array containing non-zero elements of the matrix <i>A</i>. For one-based indexing its length is $pntre(k) - pntrb(1)$. For zero-based indexing its length is $pntre(m-1) - pntrb(0)$. Refer to <i>values</i> array description in CSC Format for more details.</p>
<i>indx</i>	<p>INTEGER. Array containing the row indices for each non-zero element of the matrix <i>A</i>. Its length is equal to length of the <i>val</i> array. Refer to <i>rows</i> array description in CSC Format for more details.</p>

<i>pntrb</i>	<p>INTEGER. Array of length k.</p> <p>For one-based indexing this array contains column indices, such that $pntrb(i) - pntrb(1)+1$ is the first index of column i in the arrays <i>val</i> and <i>indx</i>.</p> <p>For zero-based indexing this array contains column indices, such that $pntrb(i) - pntrb(0)$ is the first index of column i in the arrays <i>val</i> and <i>indx</i>.</p> <p>Refer to <i>pointerb</i> array description in CSC Format for more details.</p>
<i>pntrc</i>	<p>INTEGER. Array of length k.</p> <p>For one-based indexing this array contains column indices, such that $pntrc(i) - pntrb(1)$ is the last index of column i in the arrays <i>val</i> and <i>indx</i>.</p> <p>For zero-based indexing this array contains column indices, such that $pntrc(i) - pntrb(1)-1$ is the last index of column i in the arrays <i>val</i> and <i>indx</i>.</p> <p>Refer to <i>pointerE</i> array description in CSC Format for more details.</p>
<i>b</i>	<p>REAL for mkl_scscmm. DOUBLE PRECISION for mkl_dcscmm. COMPLEX for mkl_ccscmm. DOUBLE COMPLEX for mkl_zcscmm.</p> <p>Array, DIMENSION (<i>ldb</i>, at least n for non-transposed matrix <i>A</i> and at least m for transposed) for one-based indexing, and (at least k for non-transposed matrix <i>A</i> and at least m for transposed, <i>ldb</i>) for zero-based indexing.</p> <p>On entry with <i>transa</i> = 'N' or 'n', the leading k-by-n part of the array <i>b</i> must contain the matrix <i>B</i>, otherwise the leading m-by-n part of the array <i>b</i> must contain the matrix <i>B</i>.</p>
<i>ldb</i>	<p>INTEGER. Specifies the first dimension of <i>b</i> for one-based indexing, and the second dimension of <i>b</i> for zero-based indexing, as declared in the calling (sub)program.</p>
<i>beta</i>	<p>REAL*8. Specifies the scalar <i>beta</i>.</p>
<i>c</i>	<p>REAL for mkl_scscmm. DOUBLE PRECISION for mkl_dcscmm. COMPLEX for mkl_ccscmm. DOUBLE COMPLEX for mkl_zcscmm.</p>

Array, DIMENSION (ldc, n) for one-based indexing, and (m, ldc) for zero-based indexing.

On entry, the leading m -by- n part of the array c must contain the matrix C , otherwise the leading k -by- n part of the array c must contain the matrix C .

ldc

INTEGER. Specifies the first dimension of c for one-based indexing, and the second dimension of c for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c

Overwritten by the matrix ($alpha * A * B + beta * C$) or ($alpha * A' * B + beta * C$).

```

mkl_?coomm

Computes matrix-matrix product of a sparse matrix stored in the coordinate format.

Syntax

Fortran:

```
call mkl_scoomm(transa, m, n, k, alpha, matdescra, val, rowind, colind, nnz,  
b, ldb, beta, c, ldc)
```

```
call mkl_dcoomm(transa, m, n, k, alpha, matdescra, val, rowind, colind, nnz,  
b, ldb, beta, c, ldc)
```

```
call mkl_ccoomm(transa, m, n, k, alpha, matdescra, val, rowind, colind, nnz,  
b, ldb, beta, c, ldc)
```

```
call mkl_zcoomm(transa, m, n, k, alpha, matdescra, val, rowind, colind, nnz,  
b, ldb, beta, c, ldc)
```

C:

```
mkl_scoomm(&transa, &m, &n, &k, &alpha, matdescra, val, rowind, colind, &nnz,  
b, &ldb, &beta, c, &ldc);
```

```
mkl_dcoomm(&transa, &m, &n, &k, &alpha, matdescra, val, rowind, colind, &nnz,  
b, &ldb, &beta, c, &ldc);
```

```
mkl_ccoomm(&transa, &m, &n, &k, &alpha, matdescra, val, rowind, colind, &nnz,  
b, &ldb, &beta, c, &ldc);
```

```
mkl_zcoomm(&transa, &m, &n, &k, &alpha, matdescra, val, rowind, colind, &nnz,  
b, &ldb, &beta, c, &ldc);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?coomm` routine performs a matrix-matrix operation defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * A' * B + \beta * C,$$

where:

α and β are scalars,

B and C are dense matrices, A is an m -by- k sparse matrix in the coordinate format, A' is the transpose of A .

NOTE. This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha A * B + \beta A * C$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha A' * B + \beta A * C$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>n</i>	INTEGER. Number of columns of the matrix C .
<i>k</i>	INTEGER. Number of columns of the matrix A .
<i>alpha</i>	REAL for mkl_scoomm. DOUBLE PRECISION for mkl_dcoomm. COMPLEX for mkl_ccoomm. DOUBLE COMPLEX for mkl_zcoomm. Specifies the scalar α .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .
<i>val</i>	REAL for mkl_scoomm. DOUBLE PRECISION for mkl_dcoomm. COMPLEX for mkl_ccoomm. DOUBLE COMPLEX for mkl_zcoomm.

	<p>Array of length <i>nnz</i>, contains non-zero elements of the matrix <i>A</i> in the arbitrary order.</p> <p>Refer to <i>values</i> array description in Coordinate Format for more details.</p>
<i>rowind</i>	<p>INTEGER. Array of length <i>nnz</i>, contains the row indices for each non-zero element of the matrix <i>A</i>.</p> <p>Refer to <i>rows</i> array description in Coordinate Format for more details.</p>
<i>colind</i>	<p>INTEGER. Array of length <i>nnz</i>, contains the column indices for each non-zero element of the matrix <i>A</i>. Refer to <i>columns</i> array description in Coordinate Format for more details.</p>
<i>nnz</i>	<p>INTEGER. Specifies the number of non-zero element of the matrix <i>A</i>.</p> <p>Refer to <i>nnz</i> description in Coordinate Format for more details.</p>
<i>b</i>	<p>REAL for <code>mk1_scoomm</code>. DOUBLE PRECISION for <code>mk1_dcoomm</code>. COMPLEX for <code>mk1_ccoomm</code>. DOUBLE COMPLEX for <code>mk1_zcoomm</code>.</p> <p>Array, DIMENSION (<i>ldb</i>, at least <i>n</i> for non-transposed matrix <i>A</i> and at least <i>m</i> for transposed) for one-based indexing, and (at least <i>k</i> for non-transposed matrix <i>A</i> and at least <i>m</i> for transposed, <i>ldb</i>) for zero-based indexing.</p> <p>On entry with <i>transa</i> = 'N' or 'n', the leading <i>k</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>, otherwise the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>.</p>
<i>ldb</i>	<p>INTEGER. Specifies the first dimension of <i>b</i> for one-based indexing, and the second dimension of <i>b</i> for zero-based indexing, as declared in the calling (sub)program.</p>
<i>beta</i>	<p>REAL for <code>mk1_scoomm</code>. DOUBLE PRECISION for <code>mk1_dcoomm</code>. COMPLEX for <code>mk1_ccoomm</code>. DOUBLE COMPLEX for <code>mk1_zcoomm</code>.</p> <p>Specifies the scalar <i>beta</i>.</p>
<i>c</i>	<p>REAL for <code>mk1_scoomm</code>. DOUBLE PRECISION for <code>mk1_dcoomm</code>.</p>

COMPLEX for `mkl_ccoomm`.

DOUBLE COMPLEX for `mkl_zcoomm`.

Array, DIMENSION (ldc, n) for one-based indexing, and (m, ldc) for zero-based indexing.

On entry, the leading m -by- n part of the array c must contain the matrix C , otherwise the leading k -by- n part of the array c must contain the matrix C .

ldc

INTEGER. Specifies the first dimension of c for one-based indexing, and the second dimension of c for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c

Overwritten by the matrix $(\alpha * A * B + \beta * C)$ or $(\alpha * A' * B + \beta * C)$.

Interfaces

```

```
mkl_zcsrsm(&transa, &m, &n, &alpha, matdescra, val, indx, pntrb, pntre, b,  
&ldb, c, &ldc);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?csrsm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the CSR format:

$$C := \alpha * \text{inv}(A) * B$$

or

$$C := \alpha * \text{inv}(A') * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports a CSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $C := \alpha * \text{inv}(A) * B$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * \text{inv}(A') * B$,
<i>m</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>alpha</i>	REAL for mkl_scsrsm. DOUBLE PRECISION for mkl_dcsrsm. COMPLEX for mkl_ccsrsm. DOUBLE COMPLEX for mkl_zcsrsm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .
<i>val</i>	REAL for mkl_scsrsm. DOUBLE PRECISION for mkl_dcsrsm. COMPLEX for mkl_ccsrsm. DOUBLE COMPLEX for mkl_zcsrsm. Array containing non-zero elements of the matrix <i>A</i> . For one-based indexing its length is $\text{pntrc}(m) - \text{pntrb}(1)$. For zero-based indexing its length is $\text{pntrc}(m-1) - \text{pntrb}(0)$. Refer to <i>values</i> array description in CSR Format for more details.

NOTE. The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

indx INTEGER. Array containing the column indices for each non-zero element of the matrix *A*. Its length is equal to length of the *val* array.
Refer to *columns* array description in [CSR Format](#) for more details.

NOTE. Column indices must be sorted in increasing order for each row.

pntrb INTEGER. Array of length *m*.
For one-based indexing this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of row *i* in the arrays *val* and *indx*.
For zero-based indexing this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of row *i* in the arrays *val* and *indx*. Refer to *pointerb* array description in [CSR Format](#) for more details.

pntrE INTEGER. Array of length *m*.
For one-based indexing this array contains row indices, such that $pntrE(i) - pntrb(1)$ is the last index of row *i* in the arrays *val* and *indx*.
For zero-based indexing this array contains row indices, such that $pntrE(i) - pntrb(0) - 1$ is the last index of row *i* in the arrays *val* and *indx*. Refer to *pointerE* array description in [CSR Format](#) for more details.

b REAL for mkl_scsrsm.
DOUBLE PRECISION for mkl_dcsrsm.
COMPLEX for mkl_ccsrsm.
DOUBLE COMPLEX for mkl_zcsrsm.
Array, DIMENSION (*ldb*, *n*) for one-based indexing, and (*m*, *ldb*) for zero-based indexing.

On entry the leading m -by- n part of the array b must contain the matrix B .

ldb INTEGER. Specifies the first dimension of b for one-based indexing, and the second dimension of b for zero-based indexing, as declared in the calling (sub)program.

ldc INTEGER. Specifies the first dimension of c for one-based indexing, and the second dimension of c for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c REAL*8.
Array, DIMENSION (ldc , n) for one-based indexing, and (m , ldc) for zero-based indexing.
The leading m -by- n part of the array c contains the output matrix C .

Interfaces

FORTRAN 77:

mkl_zcscsm(&transa, &m, &n, &alpha, matdescra, val, indx, pntrb, pntre, b,  
&ldb, c, &ldc);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?cscsm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the CSC format:

$$C := \alpha * \text{inv}(A) * B$$

or

$$C := \alpha * \text{inv}(A') * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports a CSC format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the system of equations. If <i>transa</i> = 'N' or 'n', then $C := \alpha * \text{inv}(A) * B$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * \text{inv}(A') * B$,
<i>m</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>alpha</i>	REAL for mkl_scscsm. DOUBLE PRECISION for mkl_dcscsm. COMPLEX for mkl_ccscsm. DOUBLE COMPLEX for mkl_zcscsm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .
<i>val</i>	REAL for mkl_scscsm. DOUBLE PRECISION for mkl_dcscsm. COMPLEX for mkl_ccscsm. DOUBLE COMPLEX for mkl_zcscsm. Array containing non-zero elements of the matrix <i>A</i> . For one-based indexing its length is $\text{pntrb}(k) - \text{pntrb}(1)$. For zero-based indexing its length is $\text{pntrb}(m-1) - \text{pntrb}(0)$. Refer to <i>values</i> array description in CSC Format for more details.

NOTE. The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

indx INTEGER. Array containing the row indices for each non-zero element of the matrix *A*. Its length is equal to length of the *val* array.
Refer to *rows* array description in [CSC Format](#) for more details.

NOTE. Row indices must be sorted in increasing order for each column.

pntrb INTEGER. Array of length *m*.
For one-based indexing this array contains column indices, such that $pntrb(I) - pntrb(1) + 1$ is the first index of column *I* in the arrays *val* and *indx*.
For zero-based indexing this array contains column indices, such that $pntrb(I) - pntrb(0)$ is the first index of column *I* in the arrays *val* and *indx*.
Refer to *pointerb* array description in [CSC Format](#) for more details.

pntrE INTEGER. Array of length *m*.
For one-based indexing this array contains column indices, such that $pntrE(I) - pntrb(1)$ is the last index of column *I* in the arrays *val* and *indx*.
For zero-based indexing this array contains column indices, such that $pntrE(I) - pntrb(1) - 1$ is the last index of column *I* in the arrays *val* and *indx*.
Refer to *pointerE* array description in [CSC Format](#) for more details.

b REAL for mkl_scscsm.
DOUBLE PRECISION for mkl_dcscsm.
COMPLEX for mkl_ccscsm.
DOUBLE COMPLEX for mkl_zcscsm.

Array, DIMENSION (ldb, n) for one-based indexing, and (m, ldb) for zero-based indexing.

On entry the leading m -by- n part of the array b must contain the matrix B .

ldb INTEGER. Specifies the first dimension of b for one-based indexing, and the second dimension of b for zero-based indexing, as declared in the calling (sub)program.

ldc INTEGER. Specifies the first dimension of c for one-based indexing, and the second dimension of c for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

c REAL for mkl_scscsm.
DOUBLE PRECISION for mkl_dcscsm.
COMPLEX for mkl_ccscsm.
DOUBLE COMPLEX for mkl_zcscsm.
Array, DIMENSION (ldc, n) for one-based indexing, and (m, ldc) for zero-based indexing.
The leading m -by- n part of the array c contains the output matrix C .

&ldb, c, &ldc);
```

```
mkl_ccoosm(&transa, &m, &n, &alpha, matdescra, val, rowind, colind, &nnz, b,  
&ldb, c, &ldc);
```

```
mkl_zcoosm(&transa, &m, &n, &alpha, matdescra, val, rowind, colind, &nnz, b,  
&ldb, c, &ldc);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?coosm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the coordinate format:

$$C := \alpha * \text{inv}(A) * B$$

or

$$C := \alpha * \text{inv}(A') * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports a coordinate format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section **“Interfaces”** below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then the matrix-matrix product is computed as $C := \alpha * \text{inv}(A) * B$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $C := \alpha * \text{inv}(A') * B$,
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>alpha</i>	REAL for mkl_scoosm. DOUBLE PRECISION for mkl_dcoosm. COMPLEX for mkl_ccoosm. DOUBLE COMPLEX for mkl_zcoosm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .
<i>val</i>	REAL for mkl_scoosm. DOUBLE PRECISION for mkl_dcoosm. COMPLEX for mkl_ccoosm. DOUBLE COMPLEX for mkl_zcoosm. Array of length <i>nnz</i> , contains non-zero elements of the matrix <i>A</i> in the arbitrary order. Refer to <i>values</i> array description in Coordinate Format for more details.
<i>rowind</i>	INTEGER. Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix <i>A</i> . Refer to <i>rows</i> array description in Coordinate Format for more details.

<i>colind</i>	INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.
<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>b</i>	REAL for <code>mkl_scoosm</code> . DOUBLE PRECISION for <code>mkl_dcoosm</code> . COMPLEX for <code>mkl_ccoosm</code> . DOUBLE COMPLEX for <code>mkl_zcoosm</code> . Array, DIMENSION (<i>ldb</i> , <i>n</i>) for one-based indexing, and (<i>m</i> , <i>ldb</i>) for zero-based indexing. Before entry the leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> .
<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> for one-based indexing, and the second dimension of <i>b</i> for zero-based indexing, as declared in the calling (sub)program.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> for one-based indexing, and the second dimension of <i>c</i> for zero-based indexing, as declared in the calling (sub)program.

Output Parameters

<i>c</i>	REAL for <code>mkl_scoosm</code> . DOUBLE PRECISION for <code>mkl_dcoosm</code> . COMPLEX for <code>mkl_ccoosm</code> . DOUBLE COMPLEX for <code>mkl_zcoosm</code> . Array, DIMENSION (<i>ldc</i> , <i>n</i>) for one-based indexing, and (<i>m</i> , <i>ldc</i>) for zero-based indexing. The leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> contains the output matrix <i>C</i> .

mkl_dcsrsm(&transa, &m, &n, &lb, &alpha, matdescra, val, indx, pntrb, pntre,
b, &ldb, c, &ldc);
```

```
mkl_ccsrsm(&transa, &m, &n, &lb, &alpha, matdescra, val, indx, pntrb, pntre,
b, &ldb, c, &ldc);
```

```
mkl_zcsrsm(&transa, &m, &n, &lb, &alpha, matdescra, val, indx, pntrb, pntre,
b, &ldb, c, &ldc);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?bsrsm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the BSR format:

$$C := \alpha * \text{inv}(A) * B$$

or

$$C := \alpha * \text{inv}(A') * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports a BSR format both with one-based indexing and zero-based indexing.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

transa CHARACTER*1. Specifies the operation.

	<p>If <i>transa</i> = 'N' or 'n', then the matrix-matrix product is computed as $C := \alpha * \text{inv}(A) * B$.</p> <p>If <i>transa</i> = 'T' or 't' or 'C' or 'c', then the matrix-vector product is computed as $C := \alpha * \text{inv}(A') * B$.</p>
<i>m</i>	INTEGER. Number of block columns of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>lb</i>	INTEGER. Size of the block in the matrix <i>A</i> .
<i>alpha</i>	<p>REAL for mkl_sbsrsm.</p> <p>DOUBLE PRECISION for mkl_dbsrsm.</p> <p>COMPLEX for mkl_cbsrsm.</p> <p>DOUBLE COMPLEX for mkl_zbsrsm.</p> <p>Specifies the scalar <i>alpha</i>.</p>
<i>matdescra</i>	<p>CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 .</p> <p>Possible combinations of element values of this parameter are given in Table 2-7 .</p>
<i>val</i>	<p>REAL for mkl_sbsrsm.</p> <p>DOUBLE PRECISION for mkl_dbsrsm.</p> <p>COMPLEX for mkl_cbsrsm.</p> <p>DOUBLE COMPLEX for mkl_zbsrsm.</p> <p>Array containing elements of non-zero blocks of the matrix <i>A</i>. Its length is equal to the <i>ABAB</i> number <i>ABAB</i> of non-zero blocks in the matrix <i>A</i> multiplied by <i>lb*lb</i>. Refer to the <i>values</i> array description in BSR Format for more details.</p>

NOTE. The non-zero elements of the given row of the matrix must be stored in the same order as they appear in the row (from left to right).

No diagonal element can be omitted from a sparse storage if the solver is called with the non-unit indicator.

<i>indx</i>	INTEGER. Array containing the column indices for each non-zero block in the matrix <i>A</i> . Its length is equal to the number of non-zero blocks in the matrix <i>A</i> . Refer to the <i>columns</i> array description in BSR Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>m</i> . For one-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(1) + 1$ is the first index of block row <i>i</i> in the array <i>indx</i> . For zero-based indexing: this array contains row indices, such that $pntrb(i) - pntrb(0)$ is the first index of block row <i>i</i> in the array <i>indx</i> . Refer to <i>pointerB</i> array description in BSR Format for more details.
<i>pntrb</i>	INTEGER. Array of length <i>m</i> . For one-based indexing this array contains row indices, such that $pntrb(i) - pntrb(1)$ is the last index of block row <i>i</i> in the array <i>indx</i> . For zero-based indexing this array contains row indices, such that $pntrb(i) - pntrb(0) - 1$ is the last index of block row <i>i</i> in the array <i>indx</i> . Refer to <i>pointerE</i> array description in BSR Format for more details.
<i>b</i>	REAL for <code>mkl_sbsrsm</code> . DOUBLE PRECISION for <code>mkl_dbsrsm</code> . COMPLEX for <code>mkl_cbsrsm</code> . DOUBLE COMPLEX for <code>mkl_zbsrsm</code> . Array, DIMENSION (<i>ldb</i> , <i>n</i>) for one-based indexing, DIMENSION (<i>m</i> , <i>ldb</i>) for zero-based indexing. On entry the leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> .
<i>ldb</i>	INTEGER. Specifies the first dimension (in blocks) of <i>b</i> as declared in the calling (sub)program.
<i>ldc</i>	INTEGER. Specifies the first dimension (in blocks) of <i>c</i> as declared in the calling (sub)program.

Output Parameters

<i>c</i>	REAL for <code>mkl_sbsrsm</code> .
----------	------------------------------------

DOUBLE PRECISION for `mkl_dbsrsm`.
COMPLEX for `mkl_cbsrsm`.
DOUBLE COMPLEX for `mkl_zbsrsm`.
Array, DIMENSION (ldc , n) for one-based indexing,
DIMENSION (m , ldc) for zero-based indexing.
The leading m -by- n part of the array c contains the output
matrix C .

Interfaces

FORTRAN 77:

SUBROUTINE mkl_sbsrsm(transa, m, n, lb, alpha, matdescra, val, indx, pntreb, pntre, b, ldb, c, ldc)

```

MKL_Complex16 *val, int *indx, int *pntrb, int *pntre, MKL_Complex16 *b, int *ldb,
MKL_Complex16 *c, int *ldc);
```

mkl_?diamv

Computes matrix - vector product for a sparse matrix in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_sdiamv(transa, m, k, alpha, matdescra, val, lval, iddiag, ndiag, x,
beta, y)
call mkl_ddiamv(transa, m, k, alpha, matdescra, val, lval, iddiag, ndiag, x,
beta, y)
call mkl_cdiamv(transa, m, k, alpha, matdescra, val, lval, iddiag, ndiag, x,
beta, y)
```

```
call mkl_zdiamv(transa, m, k, alpha, matdescra, val, lval, iddiag, ndiag, x,
beta, y)
```

C:

```
mkl_sdiamv(&transa, &m, &k, &alpha, matdescra, val, &lval, iddiag, &ndiag, x,
&beta, y);
```

```
mkl_ddiamv(&transa, &m, &k, &alpha, matdescra, val, &lval, iddiag, &ndiag, x,
&beta, y);
```

```
mkl_cdiamv(&transa, &m, &k, &alpha, matdescra, val, &lval, iddiag, &ndiag, x,
&beta, y);
```

```
mkl_zdiamv(&transa, &m, &k, &alpha, matdescra, val, &lval, iddiag, &ndiag, x,
&beta, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?diamv` routine performs a matrix-vector operation defined as

$$y := \alpha * A * x + \beta * y$$

or

$$y := \alpha * A' * x + \beta * y,$$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- k sparse matrix stored in the diagonal format, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

transa CHARACTER*1. Specifies the operation.

	<p>If <i>transa</i> = 'N' or 'n', then $y := \alpha * A * x + \beta * y$, If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * A' * x + \beta * y$.</p>
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL for <code>mkl_sdiamv</code> . DOUBLE PRECISION for <code>mkl_ddiamv</code> . COMPLEX for <code>mkl_cdiamv</code> . DOUBLE COMPLEX for <code>mkl_zdiamv</code> . Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .
<i>val</i>	REAL for <code>mkl_sdiamv</code> . DOUBLE PRECISION for <code>mkl_ddiamv</code> . COMPLEX for <code>mkl_cdiamv</code> . DOUBLE COMPLEX for <code>mkl_zdiamv</code> . Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details.
<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix <i>A</i> .
<i>x</i>	REAL for <code>mkl_sdiamv</code> . DOUBLE PRECISION for <code>mkl_ddiamv</code> . COMPLEX for <code>mkl_cdiamv</code> . DOUBLE COMPLEX for <code>mkl_zdiamv</code> .

Array, DIMENSION at least k if $transa = 'N'$ or $'n'$, and at least m otherwise. On entry, the array x must contain the vector x .

beta REAL for mkl_sdiamv.
DOUBLE PRECISION for mkl_ddiamv.
COMPLEX for mkl_cdiamv.
DOUBLE COMPLEX for mkl_zdiamv.
Specifies the scalar *beta*.

y REAL for mkl_sdiamv.
DOUBLE PRECISION for mkl_ddiamv.
COMPLEX for mkl_cdiamv.
DOUBLE COMPLEX for mkl_zdiamv.
Array, DIMENSION at least m if $transa = 'N'$ or $'n'$, and at least k otherwise. On entry, the array y must contain the vector y .

Output Parameters

y Overwritten by the updated vector y .

Interfaces

FORTRAN 77:

```

int *ndiag, MKL_Complex16 *x, MKL_Complex16 *beta, MKL_Complex16 *y);

```

mkl_?skymv

Computes matrix - vector product for a sparse matrix in the skyline storage format with one-based indexing.

Syntax**Fortran:**

```
call mkl_sskymv(transa, m, k, alpha, matdescra, val, pntr, x, beta, y)
```

```
call mkl_dskymv(transa, m, k, alpha, matdescra, val, pntr, x, beta, y)
call mkl_cskymv(transa, m, k, alpha, matdescra, val, pntr, x, beta, y)
call mkl_zskymv(transa, m, k, alpha, matdescra, val, pntr, x, beta, y)
```

C:

```
mkl_sskymv(&transa, &m, &k, &alpha, matdescra, val, pntr, x, &beta, y);
mkl_dskymv(&transa, &m, &k, &alpha, matdescra, val, pntr, x, &beta, y);
mkl_cskymv(&transa, &m, &k, &alpha, matdescra, val, pntr, x, &beta, y);
mkl_zskymv(&transa, &m, &k, &alpha, matdescra, val, pntr, x, &beta, y);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?skymv` routine performs a matrix-vector operation defined as

$$y := \alpha A x + \beta y$$

or

$$y := \alpha A' x + \beta y,$$

where:

α and β are scalars,

x and y are vectors,

A is an m -by- k sparse matrix stored using the skyline storage scheme, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

transa CHARACTER*1. Specifies the operation.
If *transa* = 'N' or 'n', then $y := \alpha A x + \beta y$

If *transa* = 'T' or 't' or 'C' or 'c', then $y := \alpha * A' * x + \beta * y$,

m INTEGER. Number of rows of the matrix *A*.

k INTEGER. Number of columns of the matrix *A*.

alpha REAL for `mkl_sskymv`.
DOUBLE PRECISION for `mkl_dskymv`.
COMPLEX for `mkl_cskymv`.
DOUBLE COMPLEX for `mkl_zskymv`.
Specifies the scalar *alpha*.

matdescra CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in [Table 2-6](#) . Possible combinations of element values of this parameter are given in [Table 2-7](#) .

NOTE. General matrices (*matdescra* (1)='G') is not supported.

val REAL for `mkl_sskymv`.
DOUBLE PRECISION for `mkl_dskymv`.
COMPLEX for `mkl_cskymv`.
DOUBLE COMPLEX for `mkl_zskymv`.
Array containing the set of elements of the matrix *A* in the skyline profile form.
If *matdescrsa*(2)= 'L', then *val* contains elements from the low triangle of the matrix *A*.
If *matdescrsa*(2)= 'U', then *val* contains elements from the upper triangle of the matrix *A*.
Refer to *values* array description in [Skyline Storage Scheme](#) for more details.

pntr INTEGER. Array of length (*m+m*) for lower triangle, and (*k+k*) for upper triangle.
It contains the indices specifying in the *val* the positions of the first element in each row (column) of the matrix *A*. Refer to *pointers* array description in [Skyline Storage Scheme](#) for more details.

<i>x</i>	REAL for <code>mkl_sskymv</code> . DOUBLE PRECISION for <code>mkl_dskymv</code> . COMPLEX for <code>mkl_cskymv</code> . DOUBLE COMPLEX for <code>mkl_zskymv</code> . Array, DIMENSION at least <i>k</i> if <i>transa</i> = 'N' or 'n' and at least <i>m</i> otherwise. On entry, the array <i>x</i> must contain the vector <i>x</i> .
<i>beta</i>	REAL for <code>mkl_sskymv</code> . DOUBLE PRECISION for <code>mkl_dskymv</code> . COMPLEX for <code>mkl_cskymv</code> . DOUBLE COMPLEX for <code>mkl_zskymv</code> . Specifies the scalar <i>beta</i> .
<i>y</i>	REAL for <code>mkl_sskymv</code> . DOUBLE PRECISION for <code>mkl_dskymv</code> . COMPLEX for <code>mkl_cskymv</code> . DOUBLE COMPLEX for <code>mkl_zskymv</code> . Array, DIMENSION at least <i>m</i> if <i>transa</i> = 'N' or 'n' and at least <i>k</i> otherwise. On entry, the array <i>y</i> must contain the vector <i>y</i> .

Output Parameters

<i>y</i>	Overwritten by the updated vector <i>y</i> .

```

mkl_?diasv

Solves a system of linear equations for a sparse matrix in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_sdiasv(transa, m, alpha, matdescra, val, lval, idiag, ndiag, x, y)
call mkl_ddiasv(transa, m, alpha, matdescra, val, lval, idiag, ndiag, x, y)
call mkl_cdiasv(transa, m, alpha, matdescra, val, lval, idiag, ndiag, x, y)
call mkl_zdiasv(transa, m, alpha, matdescra, val, lval, idiag, ndiag, x, y)
```

C:

```
mkl_sdiasv(&transa, &m, &alpha, matdescra, val, &lval, idiag, &ndiag, x, y);
mkl_ddiasv(&transa, &m, &alpha, matdescra, val, &lval, idiag, &ndiag, x, y);
mkl_cdiasv(&transa, &m, &alpha, matdescra, val, &lval, idiag, &ndiag, x, y);
mkl_zdiasv(&transa, &m, &alpha, matdescra, val, &lval, idiag, &ndiag, x, y);
```

Description

This routine is declared in `mkl_splblas.fi` for FORTRAN 77 interface and in `mkl_splblas.h` for C interface.

The `mkl_?diasv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix stored in the diagonal format:

$$y := \alpha * \text{inv}(A) * x$$

or

$$y := \alpha * \text{inv}(A') * x,$$

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $y := \alpha * \text{inv}(A) * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * \text{inv}(A') * x$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>alpha</i>	REAL for <code>mkl_sdiasv</code> . DOUBLE PRECISION for <code>mkl_ddiasv</code> . COMPLEX for <code>mkl_cdiasv</code> . DOUBLE COMPLEX for <code>mkl_zdiasv</code> . Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .

<i>val</i>	REAL for mkl_sdiasv. DOUBLE PRECISION for mkl_ddiasv. COMPLEX for mkl_cdiasv. DOUBLE COMPLEX for mkl_zdiasv. Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix A. Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix A.

NOTE. All elements of this array must be sorted in increasing order.

Refer to *distance* array description in [Diagonal Storage Scheme](#) for more details.

<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix A.
<i>x</i>	REAL for mkl_sdiasv. DOUBLE PRECISION for mkl_ddiasv. COMPLEX for mkl_cdiasv. DOUBLE COMPLEX for mkl_zdiasv. Array, DIMENSION at least <i>m</i> . On entry, the array <i>x</i> must contain the vector <i>x</i> . The elements are accessed with unit increment.
<i>y</i>	REAL for mkl_sdiasv. DOUBLE PRECISION for mkl_ddiasv. COMPLEX for mkl_cdiasv. DOUBLE COMPLEX for mkl_zdiasv. Array, DIMENSION at least <i>m</i> . On entry, the array <i>y</i> must contain the vector <i>y</i> . The elements are accessed with unit increment.

Output Parameters

y Contains solution vector x .

```

mkl_?skysv

Solves a system of linear equations for a sparse matrix in the skyline format with one-based indexing.

Syntax**Fortran:**

```

call mkl_sskysv(transa, m, alpha, matdescra, val, pntr, x, y)
call mkl_dskysv(transa, m, alpha, matdescra, val, pntr, x, y)
call mkl_cskysv(transa, m, alpha, matdescra, val, pntr, x, y)
call mkl_zskysv(transa, m, alpha, matdescra, val, pntr, x, y)

```

C:

```

mkl_sskysv(&transa, &m, &alpha, matdescra, val, pntr, x, y);
mkl_dskysv(&transa, &m, &alpha, matdescra, val, pntr, x, y);
mkl_cskysv(&transa, &m, &alpha, matdescra, val, pntr, x, y);
mkl_zskysv(&transa, &m, &alpha, matdescra, val, pntr, x, y);

```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?skysv` routine solves a system of linear equations with matrix-vector operations for a sparse matrix in the skyline storage format:

$$y := \alpha * \text{inv}(A) * x$$

or

$$y := \alpha * \text{inv}(A') * x,$$

where:

α is scalar, x and y are vectors, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $y := \alpha * \text{inv}(A) * x$ If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $y := \alpha * \text{inv}(A') * x$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>alpha</i>	REAL for <code>mkl_sskysv</code> . DOUBLE PRECISION for <code>mkl_dskysv</code> . COMPLEX for <code>mkl_cskysv</code> . DOUBLE COMPLEX for <code>mkl_zskysv</code> . Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .

NOTE. General matrices ($matdescra(1)='G'$) is not supported.

val REAL for mkl_sskysv.
 DOUBLE PRECISION for mkl_dskysv.
 COMPLEX for mkl_cskysv.
 DOUBLE COMPLEX for mkl_zskysv.
 Array containing the set of elements of the matrix *A* in the skyline profile form.
 If $matdescrsa(2)='L'$, then *val* contains elements from the low triangle of the matrix *A*.
 If $matdescrsa(2)='U'$, then *val* contains elements from the upper triangle of the matrix *A*.
 Refer to *values* array description in [Skyline Storage Scheme](#) for more details.

pntr INTEGER. Array of length $(m+m)$ for lower triangle, and $(k+k)$ for upper triangle.
 It contains the indices specifying in the *val* the positions of the first element in each row (column) of the matrix *A*. Refer to *pointers* array description in [Skyline Storage Scheme](#) for more details.

x REAL for mkl_sskysv.
 DOUBLE PRECISION for mkl_dskysv.
 COMPLEX for mkl_cskysv.
 DOUBLE COMPLEX for mkl_zskysv.
 Array, DIMENSION at least *m*.
 On entry, the array *x* must contain the vector *x*. The elements are accessed with unit increment.

y REAL for mkl_sskysv.
 DOUBLE PRECISION for mkl_dskysv.
 COMPLEX for mkl_cskysv.
 DOUBLE COMPLEX for mkl_zskysv.
 Array, DIMENSION at least *m*.
 On entry, the array *y* must contain the vector *y*. The elements are accessed with unit increment.

Output Parameters

y Contains solution vector x .

Interfaces

FORTRAN 77:

float *val, int *pntnr, float *x, float *y);
void mkl_dskysv(char *transa, int *m, double *alpha, char *matdescra,
double *val, int *pntnr, double *x, double *y);
void mkl_cskysv(char *transa, int *m, MKL_Complex8 *alpha, char *matdescra,
MKL_Complex8 *val, int *pntnr, MKL_Complex8 *x, MKL_Complex8 *y);
void mkl_zskysv(char *transa, int *m, MKL_Complex16 *alpha, char *matdescra,
MKL_Complex16 *val, int *pntnr, MKL_Complex16 *x, MKL_Complex16 *y);
```

mkl_?diamm

Computes matrix-matrix product of a sparse matrix stored in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_sdiamm(transa, m, n, k, alpha, matdescra, val, lval, idiag, ndiag,
b, ldb, beta, c, ldc)
call mkl_ddiamm(transa, m, n, k, alpha, matdescra, val, lval, idiag, ndiag,
b, ldb, beta, c, ldc)
call mkl_cdiamm(transa, m, n, k, alpha, matdescra, val, lval, idiag, ndiag,
b, ldb, beta, c, ldc)
call mkl_zdiamm(transa, m, n, k, alpha, matdescra, val, lval, idiag, ndiag,
b, ldb, beta, c, ldc)
```

C:

```
mkl_sdiamm(&transa, &m, &n, &k, &alpha, matdescra, val, &lval, idiag, &ndiag,
b, &ldb, &beta, c, &ldc);
```

```
mkl_ddiamm(&transa, &m, &n, &k, &alpha, matdescra, val, &lval, idiag, &ndiag,
b, &ldb, &beta, c, &ldc);
```

```
mkl_cdiamm(&transa, &m, &n, &k, &alpha, matdescra, val, &lval, idiag, &ndiag,
b, &ldb, &beta, c, &ldc);
```

```
mkl_zdiamm(&transa, &m, &n, &k, &alpha, matdescra, val, &lval, idiag, &ndiag,
b, &ldb, &beta, c, &ldc);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?diamm` routine performs a matrix-matrix operation defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * A' * B + \beta * C,$$

where:

alpha and *beta* are scalars,

B and *C* are dense matrices, *A* is an *m*-by-*k* sparse matrix in the diagonal format, *A'* is the transpose of *A*.

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$, If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * A' * B + \beta * C$.
---------------	--

<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>k</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>alpha</i>	REAL for mkl_sdiamm. DOUBLE PRECISION for mkl_ddiamm. COMPLEX for mkl_cdiamm. DOUBLE COMPLEX for mkl_zdiamm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .
<i>val</i>	REAL for mkl_sdiamm. DOUBLE PRECISION for mkl_ddiamm. COMPLEX for mkl_cdiamm. DOUBLE COMPLEX for mkl_zdiamm. Two-dimensional array of size <i>lval</i> by <i>ndiag</i> , contains non-zero diagonals of the matrix <i>A</i> . Refer to <i>values</i> array description in Diagonal Storage Scheme for more details.
<i>lval</i>	INTEGER. Leading dimension of <i>val</i> , $lval \geq m$. Refer to <i>lval</i> description in Diagonal Storage Scheme for more details.
<i>idiag</i>	INTEGER. Array of length <i>ndiag</i> , contains the distances between main diagonal and each non-zero diagonals in the matrix <i>A</i> . Refer to <i>distance</i> array description in Diagonal Storage Scheme for more details.
<i>ndiag</i>	INTEGER. Specifies the number of non-zero diagonals of the matrix <i>A</i> .
<i>b</i>	REAL for mkl_sdiamm. DOUBLE PRECISION for mkl_ddiamm. COMPLEX for mkl_cdiamm. DOUBLE COMPLEX for mkl_zdiamm. Array, DIMENSION (<i>ldb</i> , <i>n</i>).

	On entry with <i>transa</i> = 'N' or 'n', the leading <i>k</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> , otherwise the leading <i>m</i> -by- <i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i> .
<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program.
<i>beta</i>	REAL for mkl_sdiamm. DOUBLE PRECISION for mkl_ddiamm. COMPLEX for mkl_cdiamm. DOUBLE COMPLEX for mkl_zdiamm. Specifies the scalar <i>beta</i> .
<i>c</i>	REAL for mkl_sdiamm. DOUBLE PRECISION for mkl_ddiamm. COMPLEX for mkl_cdiamm. DOUBLE COMPLEX for mkl_zdiamm. Array, DIMENSION (<i>ldc</i> , <i>n</i>). On entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> , otherwise the leading <i>k</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> .
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program.

Output Parameters

<i>c</i>	Overwritten by the matrix ($\alpha * A * B + \beta * C$) or ($\alpha * A' * B + \beta * C$).

```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?skymm` routine performs a matrix-matrix operation defined as

$$C := \alpha * A * B + \beta * C$$

or

$$C := \alpha * A' * B + \beta * C,$$

where:

α and β are scalars,

B and C are dense matrices, A is an m -by- k sparse matrix in the skyline storage format, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the operation. If <i>transa</i> = 'N' or 'n', then $C := \alpha * A * B + \beta * C$, If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * A' * B + \beta * C$,
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>n</i>	INTEGER. Number of columns of the matrix C .
<i>k</i>	INTEGER. Number of columns of the matrix A .
<i>alpha</i>	REAL for mkl_sskymm. DOUBLE PRECISION for mkl_dskymm. COMPLEX for mkl_cskymm. DOUBLE COMPLEX for mkl_zskymm. Specifies the scalar α .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .
	 <p>NOTE. General matrices (<i>matdescra</i> (1)='G') is not supported.</p>
<i>val</i>	REAL for mkl_sskymm.

	<p>DOUBLE PRECISION for <code>mkl_dskyymm</code>. COMPLEX for <code>mkl_cskyymm</code>. DOUBLE COMPLEX for <code>mkl_zskyymm</code>. Array containing the set of elements of the matrix A in the skyline profile form. If <code>matdescrsa(2) = 'L'</code>, then <code>val</code> contains elements from the low triangle of the matrix A. If <code>matdescrsa(2) = 'U'</code>, then <code>val</code> contains elements from the upper triangle of the matrix A. Refer to <code>values</code> array description in Skyline Storage Scheme for more details.</p>
<code>pntr</code>	<p>INTEGER. Array of length $(m+m)$ for lower triangle, and $(k+k)$ for upper triangle. It contains the indices specifying in the <code>val</code> the positions of the first element in each row (column) of the matrix A. Refer to <code>pointers</code> array description in Skyline Storage Scheme for more details.</p>
<code>b</code>	<p>REAL for <code>mkl_sskyymm</code>. DOUBLE PRECISION for <code>mkl_dskyymm</code>. COMPLEX for <code>mkl_cskyymm</code>. DOUBLE COMPLEX for <code>mkl_zskyymm</code>. Array, DIMENSION (<code>ldb</code>, <code>n</code>). On entry with <code>transa = 'N'</code> or <code>'n'</code>, the leading k-by-n part of the array <code>b</code> must contain the matrix B, otherwise the leading m-by-n part of the array <code>b</code> must contain the matrix B.</p>
<code>ldb</code>	<p>INTEGER. Specifies the first dimension of <code>b</code> as declared in the calling (sub)program.</p>
<code>beta</code>	<p>REAL for <code>mkl_sskyymm</code>. DOUBLE PRECISION for <code>mkl_dskyymm</code>. COMPLEX for <code>mkl_cskyymm</code>. DOUBLE COMPLEX for <code>mkl_zskyymm</code>. Specifies the scalar <code>beta</code>.</p>
<code>c</code>	<p>REAL for <code>mkl_sskyymm</code>. DOUBLE PRECISION for <code>mkl_dskyymm</code>. COMPLEX for <code>mkl_cskyymm</code>. DOUBLE COMPLEX for <code>mkl_zskyymm</code>. Array, DIMENSION (<code>ldc</code>, <code>n</code>).</p>

On entry, the leading m -by- n part of the array c must contain the matrix C , otherwise the leading k -by- n part of the array c must contain the matrix C .

ldc INTEGER. Specifies the first dimension of c as declared in the calling (sub)program.

Output Parameters

c Overwritten by the matrix $(\alpha * A * B + \beta * C)$ or $(\alpha * A' * B + \beta * C)$.

Interfaces

FORTRAN 77:

MKL_Complex16 *beta, MKL_Complex16 *c, int *ldc);
```

mkl_?diasm

Solves a system of linear matrix equations for a sparse matrix in the diagonal format with one-based indexing.

Syntax

Fortran:

```
call mkl_sdiasm(transa, m, n, alpha, matdescra, val, lval, idiag, ndiag, b,  
ldb, c, ldc)
```

```
call mkl_ddiasm(transa, m, n, alpha, matdescra, val, lval, idiag, ndiag, b,  
ldb, c, ldc)
```

```
call mkl_cdiasm(transa, m, n, alpha, matdescra, val, lval, idiag, ndiag, b,  
ldb, c, ldc)
```

```
call mkl_zdiasm(transa, m, n, alpha, matdescra, val, lval, idiag, ndiag, b,  
ldb, c, ldc)
```

C:

```
mkl_ddiasm(&transa, &m, &n, &alpha, matdescra, val, &lval, idiag, &ndiag, b,  
&ldb, c, &ldc);
```

```
mkl_ddiasm(&transa, &m, &n, &alpha, matdescra, val, &lval, idiag, &ndiag, b,  
&ldb, c, &ldc);
```

```
mkl_ddiasm(&transa, &m, &n, &alpha, matdescra, val, &lval, idiag, &ndiag, b,  
&ldb, c, &ldc);
```

```
mkl_ddiasm(&transa, &m, &n, &alpha, matdescra, val, &lval, idiag, &ndiag, b,  
&ldb, c, &ldc);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?diasm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the diagonal format:

$$C := \alpha * \text{inv}(A) * B$$

or

$$C := \alpha * \text{inv}(A') * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $C := \alpha * \text{inv}(A) * B$, If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * \text{inv}(A') * B$.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>n</i>	INTEGER. Number of columns of the matrix C .
<i>alpha</i>	REAL for mkl_sdiasm. DOUBLE PRECISION for mkl_ddiasm. COMPLEX for mkl_cdiasm. DOUBLE COMPLEX for mkl_zdiasm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .
<i>val</i>	REAL for mkl_sdiasm. DOUBLE PRECISION for mkl_ddiasm. COMPLEX for mkl_cdiasm. DOUBLE COMPLEX for mkl_zdiasm.

Two-dimensional array of size $lval$ by $ndiag$, contains non-zero diagonals of the matrix A . Refer to *values* array description in [Diagonal Storage Scheme](#) for more details.

lval INTEGER. Leading dimension of *val*, $lval \geq m$. Refer to *lval* description in [Diagonal Storage Scheme](#) for more details.

idiag INTEGER. Array of length $ndiag$, contains the distances between main diagonal and each non-zero diagonals in the matrix A .

NOTE. All elements of this array must be sorted in increasing order.

Refer to *distance* array description in [Diagonal Storage Scheme](#) for more details.

ndiag INTEGER. Specifies the number of non-zero diagonals of the matrix A .

b REAL for `mkl_sdiasm`.
 DOUBLE PRECISION for `mkl_ddiasm`.
 COMPLEX for `mkl_cdiasm`.
 DOUBLE COMPLEX for `mkl_zdiasm`.
 Array, DIMENSION (ldb, n).
 On entry the leading m -by- n part of the array b must contain the matrix B .

ldb INTEGER. Specifies the first dimension of b as declared in the calling (sub)program.

ldc INTEGER. Specifies the first dimension of c as declared in the calling (sub)program.

Output Parameters

c REAL for `mkl_sdiasm`.
 DOUBLE PRECISION for `mkl_ddiasm`.
 COMPLEX for `mkl_cdiasm`.
 DOUBLE COMPLEX for `mkl_zdiasm`.
 Array, DIMENSION (ldc, n).

The leading m -by- n part of the array c contains the matrix C .

```

mkl_?skysm

Solves a system of linear matrix equations for a sparse matrix stored using the skyline storage scheme with one-based indexing.

Syntax**Fortran:**

```
call mkl_sskysm(transa, m, n, alpha, matdescra, val, pntr, b, ldb, c, ldc)
```

```
call mkl_dskysm(transa, m, n, alpha, matdescra, val, pntr, b, ldb, c, ldc)
call mkl_cksysm(transa, m, n, alpha, matdescra, val, pntr, b, ldb, c, ldc)
call mkl_zskysm(transa, m, n, alpha, matdescra, val, pntr, b, ldb, c, ldc)
```

C:

```
mkl_sskysm(&transa, &m, &n, &alpha, matdescra, val, pntr, b, &ldb, c, &ldc);
mkl_dskysm(&transa, &m, &n, &alpha, matdescra, val, pntr, b, &ldb, c, &ldc);
mkl_cksysm(&transa, &m, &n, &alpha, matdescra, val, pntr, b, &ldb, c, &ldc);
mkl_zskysm(&transa, &m, &n, &alpha, matdescra, val, pntr, b, &ldb, c, &ldc);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?skysm` routine solves a system of linear equations with matrix-matrix operations for a sparse matrix in the skyline storage format:

$$C := \alpha * \text{inv}(A) * B$$

or

$$C := \alpha * \text{inv}(A') * B,$$

where:

α is scalar, B and C are dense matrices, A is a sparse upper or lower triangular matrix with unit or non-unit main diagonal, A' is the transpose of A .

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>transa</i>	CHARACTER*1. Specifies the system of linear equations. If <i>transa</i> = 'N' or 'n', then $C := \alpha * \text{inv}(A) * B$, If <i>transa</i> = 'T' or 't' or 'C' or 'c', then $C := \alpha * \text{inv}(A') * B$,
---------------	---

<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>C</i> .
<i>alpha</i>	REAL for mkl_sskysm. DOUBLE PRECISION for mkl_dskysm. COMPLEX for mkl_cskysm. DOUBLE COMPLEX for mkl_zskysm. Specifies the scalar <i>alpha</i> .
<i>matdescra</i>	CHARACTER. Array of six elements, specifies properties of the matrix used for operation. Only first four array elements are used, their possible values are given in Table 2-6 . Possible combinations of element values of this parameter are given in Table 2-7 .

NOTE. General matrices (*matdescra*(1)='G') is not supported.

<i>val</i>	REAL for mkl_sskysm. DOUBLE PRECISION for mkl_dskysm. COMPLEX for mkl_cskysm. DOUBLE COMPLEX for mkl_zskysm. Array containing the set of elements of the matrix <i>A</i> in the skyline profile form. If <i>matdescrsa</i> (2)= 'L', then <i>val</i> contains elements from the low triangle of the matrix <i>A</i> . If <i>matdescrsa</i> (2)= 'U', then <i>val</i> contains elements from the upper triangle of the matrix <i>A</i> . Refer to <i>values</i> array description in Skyline Storage Scheme for more details.
<i>pntr</i>	INTEGER. Array of length (<i>m+m</i>). It contains the indices specifying in the <i>val</i> the positions of the first non-zero element of each <i>i</i> -row (column) of the matrix <i>A</i> such that <i>pointers</i> (<i>i</i>)- <i>pointers</i> (1)+1. Refer to <i>pointers</i> array description in Skyline Storage Scheme for more details.
<i>b</i>	REAL for mkl_sskysm. DOUBLE PRECISION for mkl_dskysm. COMPLEX for mkl_cskysm.

DOUBLE COMPLEX for `mkl_zskysm`.

Array, DIMENSION (`ldb`, `n`).

On entry the leading m -by- n part of the array b must contain the matrix B .

ldb

INTEGER. Specifies the first dimension of b as declared in the calling (sub)program.

ldc

INTEGER. Specifies the first dimension of c as declared in the calling (sub)program.

Output Parameters

c

REAL for `mkl_sskysm`.

DOUBLE PRECISION for `mkl_dskysm`.

COMPLEX for `mkl_cskysm`.

DOUBLE COMPLEX for `mkl_zskysm`.

Array, DIMENSION (`ldc`, `n`).

The leading m -by- n part of the array c contains the matrix C .

Interfaces

FORTRAN 77:

MKL_Complex16 *val, int *pntnr, MKL_Complex16 *b, int *ldb, MKL_Complex16 *c, int *ldc);
```

mkl_ddnscsr

Convert a sparse matrix in dense representation to the CSR format and vice versa.

Syntax

Fortran:

```
call mkl_ddnscsr(job, m, n, adns, lda, acsr, ja, ia, info)
```

C:

```
mkl_ddnscsr(job, &m, &n, adns, &lda, acsr, ja, ia, &info);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

This routine converts an sparse matrix stored as a rectangular m-by-n matrix *A* (dense representation) to the compressed sparse row (CSR) format (3-array variation) and vice versa.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>job</i>	<p>INTEGER Array, contains the following conversion parameters:</p> <p><i>job</i>(1) If <i>job</i>(1)=0, the rectangular matrix <i>A</i> is converted to the CSR format; if <i>job</i>(1)=1, the rectangular matrix <i>A</i> is restored from the CSR format.</p> <p><i>job</i>(2) If <i>job</i>(2)=0, zero-based indexing for the rectangular matrix <i>A</i> is used; if <i>job</i>(2)=1, one-based indexing for the rectangular matrix <i>A</i> is used.</p> <p><i>job</i>(3) If <i>job</i>(3)=0, zero-based indexing for the matrix in CSR format is used; if <i>job</i>(3)=1, one-based indexing for the matrix in CSR format is used.</p> <p><i>job</i>(4) If <i>job</i>(4)=0, <i>adns</i> is a lower triangular part of matrix <i>A</i>; If <i>job</i>(4)=1, <i>adns</i> is an upper triangular part of matrix <i>A</i>; If <i>job</i>(4)=2, <i>adns</i> is a whole matrix <i>A</i>.</p> <p><i>job</i>(5) <i>job</i>(5)=<i>nzmax</i> - maximum number of the non-zero elements allowed if <i>job</i>(1)=0.</p> <p><i>job</i>(6) - job indicator for conversion to CSR format. If <i>job</i>(6)=0, only array <i>ia</i> is generated for the output storage. If <i>job</i>(6)>0, arrays <i>acsr</i>, <i>ia</i>, <i>ja</i> are generated for the output storage.</p>
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>adns</i>	(input/output)DOUBLE PRECISION. Array containing non-zero elements of the matrix <i>A</i> .

<i>lda</i>	(input/output)INTEGER. Specifies the first dimension of <i>adns</i> as declared in the calling (sub)program, must be at least $\max(1, m)$.
<i>acsr</i>	(input/output)DOUBLE PRECISION. Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	(input/output)INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>acsr</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	(input/output)INTEGER. Array of length $m + 1$, containing indices of elements in the array <i>acsr</i> , such that $ia(I)$ is the index in the array <i>acsr</i> of the first non-zero element from the row <i>I</i> . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.

Output Parameters

<i>info</i>	INTEGER. Integer info indicator only for restoring the matrix <i>A</i> from the CSR format. If $info=0$, the execution is successful. If $info=i$, the routine is interrupted processing the <i>i</i> -th row because there is no space in the arrays <i>adns</i> and <i>ja</i> according to the value <i>nzmax</i> .
-------------	---

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_ddnscsr(job, m, n, adns, lda, acsr, ja, ia, info)
    INTEGER      job(8)
    INTEGER      m, n, lda, info
    INTEGER      ja(*), ia(m+1)
    DOUBLE PRECISION  adns(*), acsr(*)
```

C:

```
void mkl_ddnscsr(int *job, int *m, int *n, double *adns,
int *lda, double *acsr, int *ja, int *ia, int *info);
```

mkl_dcsrcoo

Converts a sparse matrix in the CSR format to the coordinate format and vice versa.

Syntax

Fortran:

```
call mkl_dcsrcoo(job, n, acsr, ja, ia, nnz, acoo, rowind, colind, info)
```

C:

```
mkl_dcsrcoo(job, &n, acsr, ja, ia, &nnz, acoo, rowind, colind, &info);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

This routine converts a sparse matrix *A* stored in the compressed sparse row (CSR) format (3-array variation) to coordinate format and vice versa.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

job INTEGER
Array, contains the following conversion parameters:

job(1)
If *job(1)*=0, the matrix in the CSR format is converted to the coordinate format;
if *job(1)*=1, the matrix in the coordinate format is converted to the CSR format.

job(2)
If *job(2)*=0, zero-based indexing for the matrix in CSR format is used;
if *job(2)*=1, one-based indexing for the matrix in CSR format is used.

job(3)
If *job(3)*=0, zero-based indexing for the matrix in coordinate format is used;
if *job(3)*=1, one-based indexing for the matrix in coordinate format is used.

job(5)
job(5)=*nzmax* - maximum number of the non-zero elements allowed if *job(1)*=0.
job(5)=*nnz* - sets number of the non-zero elements of the matrix A if *job(1)*=1.

job(6) - job indicator.
For conversion to the coordinate format:
If *job(6)*=1, only array *rowind* is filled in for the output storage.
If *job(6)*=2, arrays *rowind*, *colind* are filled in for the output storage.
If *job(6)*=3, all arrays *rowind*, *colind*, *acoo* are filled in for the output storage.
For conversion to the CSR format:
If *job(6)*=0, all arrays *acsr*, *ja*, *ia* are filled in for the output storage.
If *job(6)*=1, only array *ia* is filled in for the output storage.

If $job(6)=2$, then it is assumed that the routine already has been called with the $job(6)=1$, and the user allocated the required space for storing the output arrays *acsr* and *ja*.

<i>n</i>	INTEGER. Dimension of the matrix <i>A</i> .
<i>acsr</i>	(input/output) DOUBLE PRECISION. Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	(input/output) INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>acsr</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	(input/output) INTEGER. Array of length $n + 1$, containing indices of elements in the array <i>acsr</i> , such that $ia(I)$ is the index in the array <i>acsr</i> of the first non-zero element from the row <i>I</i> . The value of the last element $ia(n + 1)$ is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
<i>acoo</i>	(input/output) DOUBLE PRECISION. Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>rowind</i>	(input/output) INTEGER. Array of length <i>nnz</i> , contains the row indices for each non-zero element of the matrix <i>A</i> . Refer to <i>rows</i> array description in Coordinate Format for more details.
<i>colind</i>	(input/output) INTEGER. Array of length <i>nnz</i> , contains the column indices for each non-zero element of the matrix <i>A</i> . Refer to <i>columns</i> array description in Coordinate Format for more details.

Output Parameters

<i>nnz</i>	INTEGER. Specifies the number of non-zero element of the matrix <i>A</i> . Refer to <i>nnz</i> description in Coordinate Format for more details.
<i>info</i>	INTEGER. Integer info indicator only for converting the matrix <i>A</i> from the CSR format. If <i>info</i> =0, the execution is successful. If <i>info</i> =1, the routine is interrupted because there is no space in the arrays <i>acoo</i> , <i>rowind</i> , <i>colind</i> according to the value <i>nzmax</i> .

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcsrcoo(job, n, acsr, ja, ia, nnz, acoo, rowind, colind, info)
    INTEGER      job(8)
    INTEGER      n, nnz, info
    INTEGER      ja(*), ia(n+1), rowind(*), colind(*)
    DOUBLE PRECISION  acsr(*), acoo(*)
```

C:

```
void mkl_dcsrcoo(int *job, int *n, double *acsr, int *ja,
int *ia, int *nnz, double *acoo, int *rowind, int *colind, int *info);
```

mkl_dcsrbsr

Converts a sparse matrix in the CSR format to the BSR format and vice versa.

Syntax

Fortran:

```
call mkl_dcsrbsr(job, m, mblk, ldabsr, acsr, ja, ia, absr, jab, iab, info)
```

C:

```
mkl_dcsrbsr(job, &m, &mblk, &ldabsr, acsr, ja, ia, absr, jab, iab, &info);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

This routine converts a sparse matrix *A* stored in the compressed sparse row (CSR) format (3-array variation) to the block sparse row (BSR) format and vice versa.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

job INTEGER
 Array, contains the following conversion parameters:

job(1)
 If *job*(1)=0, the matrix in the CSR format is converted to the BSR format;
 if *job*(1)=1, the matrix in the BSR format is converted to the CSR format.

job(2)
 If *job*(2)=0, zero-based indexing for the matrix in CSR format is used;
 if *job*(2)=1, one-based indexing for the matrix in CSR format is used.

job(3)
 If *job*(3)=0, zero-based indexing for the matrix in the BSR format is used;
 if *job*(3)=1, one-based indexing for the matrix in the BSR format is used.

job(6) - job indicator.
 For conversion to the BSR format:
 If *job*(6)=0, only arrays *jab*, *iab* are generated for the output storage.
 If *job*(6)>0, all output arrays *absr*, *jab*, and *iab* are filled in for the output storage.

If $job(6)=-1$, $iab(1)$ returns the number of non-zero blocks.

For conversion to the CSR format:

If $job(6)=0$, only arrays ja , ia are generated for the output storage.

m	INTEGER. Actual row dimension of the matrix A for convert to the BSR format; block row dimension of the matrix A for convert to the CSR format.
$mblk$	INTEGER. Size of the block in the matrix A .
$ldabsr$	INTEGER. Leading dimension of the array $absr$ as declared in the calling program. $ldabsr$ must be greater than or equal to $mblk*mblk$.
$acsr$	(input/output) DOUBLE PRECISION. Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
ja	(input/output) INTEGER. Array containing the column indices for each non-zero element of the matrix A . Its length is equal to the length of the array $acsr$. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
ia	(input/output) INTEGER. Array of length $m + 1$, containing indices of elements in the array $acsr$, such that $ia(I)$ is the index in the array $acsr$ of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
$absr$	(input/output) DOUBLE PRECISION. Array containing elements of non-zero blocks of the matrix A . Its length is equal to the number of non-zero blocks in the matrix A multiplied by $mblk*mblk$. Refer to <i>values</i> array description in BSR Format for more details.
jab	(input/output) INTEGER. Array of length $(m + 1)$, containing indices of block in the array $absr$, such that $ja(i)$ is the index in the array $absr$ of the first non-zero element from

the i -th row . The value of the last element $jab(m + 1)$ is equal to the number of non-zero blocks plus one. Refer to *rowIndex* array description in [BSR Format](#) for more details.

iab (input/output) INTEGER. Array containing the column indices for each non-zero block of the matrix A . Its length is equal to the number of non-zero blocks of the matrix A . Refer to *columns* array description in [BSR Format](#) for more details.

Output Parameters

info INTEGER. Integer info indicator only for converting the matrix A from the CSR format.

If *info*=0, the execution is successful.

If *info*=1, it means that *mblk* is equal to 0.

If *info*=2, it means that *ldabsr* is less than *mblk***mblk* and there is no space for all blocks.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcsrbsr(job, m, mblk, ldabsr, acsr, ja, ia, absr, jab, iab, info)
    INTEGER      job(8)
    INTEGER      m, mblk, ldabsr, info
    INTEGER      ja(*), ia(m+1), jab(*), iab(*)
    DOUBLE PRECISION  acsr(*), absr(ldabsr,*)
```

C:

```
void mkl_dcsrbsr(int *job, int *m, int *mblk, int *ldabsr, double *acsr, int *ja,
int *ia, double *absr, int *jab, int *iab, int *info);
```

mkl_dcsrsc

Converts a sparse matrix in the CSR format to the CSC format and vice versa.

Syntax

Fortran:

```
call mkl_dcsrsc(job, m, acsr, ja, ia, acsc, ja1, ia1, info)
```

C:

```
mkl_dcsrsc(job, &m, acsr, ja, ia, acsc, ja1, ia1, &info);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

This routine converts a sparse matrix *A* stored in the compressed sparse row (CSR) format (3-array variation) to the compressed sparse column (CSC) format and vice versa.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>job</i>	INTEGER
	Array, contains the following conversion parameters:
<i>job</i> (1)	If <i>job</i> (1)=0, the matrix in the CSR format is converted to the CSC format; if <i>job</i> (1)=1, the matrix in the CSC format is converted to the CSR format.
<i>job</i> (2)	If <i>job</i> (2)=0, zero-based indexing for the matrix in CSR format is used; if <i>job</i> (2)=1, one-based indexing for the matrix in CSR format is used.
<i>job</i> (3)	If <i>job</i> (3)=0, zero-based indexing for the matrix in the CSC format is used;

if $job(3)=1$, one-based indexing for the matrix in the CSC format is used.

$job(6)$ - job indicator.

For conversion to the CSC format:

If $job(6)=0$, all output arrays $acsc$, $ja1$, and $ia1$ are filled in for the output storage.

If $job(6)\neq 0$, only arrays $ja1$, $ia1$ are filled in for the output storage.

For conversion to the CSR format:

If $job(6)=0$, all output arrays $acsr$, ja , and ia are filled in for the output storage.

If $job(6)\neq 0$, only arrays ja , ia are filled in for the output storage.

m	INTEGER. Dimension of the matrix A .
$acsr$	(input/output) DOUBLE PRECISION. Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
ja	(input/output) INTEGER. Array containing the column indices for each non-zero element of the matrix A . Its length is equal to the length of the array $acsr$. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
ia	(input/output) INTEGER. Array of length $m + 1$, containing indices of elements in the array $acsr$, such that $ia(I)$ is the index in the array $acsr$ of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
$acsc$	(input/output) DOUBLE PRECISION. Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.

<i>ja1</i>	(input/output) INTEGER. Array containing the row indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>acsc</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia1</i>	(input/output) INTEGER. Array of length $m + 1$, containing indices of elements in the array <i>acsc</i> , such that $ia(I)$ is the index in the array <i>acsc</i> of the first non-zero element from the row <i>I</i> . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.

Output Parameters

info INTEGER. This parameter is not used now.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcsrsc(job, m, acsr, ja, ia, acsc, ja1, ia1, info)
    INTEGER      job(8)
    INTEGER      m, info
    INTEGER      ja(*), ia(m+1), ja1(*), ia1(m+1)
    DOUBLE PRECISION  acsr(*), acsc(*)
```

C:

```
void mkl_dcsrsc(int *job, int *m, double *acsr, int *ja,
int *ia, double *acsc, int *ja1, int *ia1, int *info);
```

mkl_dcsrda

Converts a sparse matrix in the CSR format to the diagonal format and vice versa.

Syntax

Fortran:

```
call mkl_dcsrda(job, m, acsr, ja, ia, adia, ndiag, distance, idiag, acsr_rem,  
ja_rem, ia_rem, info)
```

C:

```
mkl_dcsrda(job, &m, acsr, ja, ia, adia, &ngiag, distance, &idiag, acsr_rem,  
ja_rem, ia_rem, &info);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

This routine converts a sparse matrix A stored in the compressed sparse row (CSR) format (3-array variation) to the diagonal format and vice versa.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>job</i>	INTEGER Array, contains the following conversion parameters: <i>job</i> (1) If <i>job</i> (1)=0, the matrix in the CSR format is converted to the diagonal format; if <i>job</i> (1)=1, the matrix in the diagonal format is converted to the CSR format. <i>job</i> (2) If <i>job</i> (2)=0, zero-based indexing for the matrix in CSR format is used; if <i>job</i> (2)=1, one-based indexing for the matrix in CSR format is used. <i>job</i> (3)
------------	--

If $job(3)=0$, zero-based indexing for the matrix in the diagonal format is used;

if $job(3)=1$, one-based indexing for the matrix in the diagonal format is used.

$job(6)$ - job indicator.

For conversion to the diagonal format:

If $job(6)=0$, diagonals are not selected internally, and $acsr_rem$, ja_rem , ia_rem are not filled in for the output storage.

If $job(6)=1$, diagonals are not selected internally, and $acsr_rem$, ja_rem , ia_rem are filled in for the output storage.

If $job(6)=10$, diagonals are selected internally, and $acsr_rem$, ja_rem , ia_rem are not filled in for the output storage.

If $job(6)=11$, diagonals are selected internally, and csr_rem , ja_rem , ia_rem are filled in for the output storage.

For conversion to the CSR format:

If $job(6)=0$, each entry in the array $adia$ is checked whether it is zero. Zero entries are not included in the array $acsr$.

If $job(6)\neq 0$, each entry in the array $adia$ is not checked whether it is zero.

m	INTEGER. Dimension of the matrix A .
$acsr$	(input/output) DOUBLE PRECISION. Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
ja	(input/output) INTEGER. Array containing the column indices for each non-zero element of the matrix A . Its length is equal to the length of the array $acsr$. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
ia	(input/output) INTEGER. Array of length $m + 1$, containing indices of elements in the array $acsr$, such that $ia(I)$ is the index in the array $acsr$ of the first non-zero element

from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

<i>adia</i>	(input/output) DOUBLE PRECISION. Array of size (<i>ndiag</i> × <i>idiag</i>) containing diagonals of the matrix <i>A</i> . The key point of the storage is that each element in the array <i>adia</i> retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom.
<i>ndiag</i>	INTEGER. Specifies the first dimension of the array <i>adia</i> as declared in the calling (sub)program, must be at least $\max(1, m)$.
<i>distance</i>	INTEGER. Array of length <i>idiag</i> , containing the distances between the main diagonal and each non-zero diagonal to be extracted. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.
<i>idiag</i>	INTEGER. Number of diagonals to be extracted. For conversion to diagonal format on return this parameter may be modified.
<i>acsr_rem, ja_rem, ia_rem</i>	Remainder of the matrix in the CSR format if it is needed for conversion to the diagonal format.

Output Parameters

<i>info</i>	INTEGER. This parameter is not used now.
-------------	--

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcsrsc(job, m, acsr, ja, ia, adia, ndiag, distance, idiag, acsr_rem, ja_rem,
  ia_rem, info)

  INTEGER      job(8)

  INTEGER      m, info, ndiag, idiag

  INTEGER      ja(*), ia(m+1), distance(*), ja_rem(*), ia_rem(*)

  DOUBLE PRECISION  acsr(*), adia(*), acsr_rem(*)
```

C:

```
void mkl_dcsrdia(int *job, int *m, double *acsr, int *ja,
  int *ia, double *adia, int *ndiag, int *distance, int *distance,
  int *idiag, double *acsr_rem, int *ja_rem, int *ia_rem, int *info);
```

mkl_dcsrsky

Converts a sparse matrix in CSR format to the skyline format and vice versa.

Syntax

Fortran:

```
call mkl_dcsrsky(job, m, acsr, ja, ia, asky, pointers, info)
```

C:

```
mkl_dcsrsky(job, &m, acsr, ja, ia, asky, pointers, &info);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

This routine converts a sparse matrix *A* stored in the compressed sparse row (CSR) format (3-array variation) to the skyline format and vice versa.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

job

INTEGER

Array, contains the following conversion parameters:

job(1)

If *job*(1)=0, the matrix in the CSR format is converted to the skyline format;

if *job*(1)=1, the matrix in the skyline format is converted to the CSR format.

job(2)

If *job*(2)=0, zero-based indexing for the matrix in CSR format is used;

if *job*(2)=1, one-based indexing for the matrix in CSR format is used.

job(3)

If *job*(3)=0, zero-based indexing for the matrix in the skyline format is used;

if *job*(3)=1, one-based indexing for the matrix in the skyline format is used.

job(4)

For conversion to the skyline format:

If *job*(4)=0, the upper part of the matrix *A* in the CSR format is converted.

If *job*(4)=1, the lower part of the matrix *A* in the CSR format is converted.

For conversion to the CSR format:

If *job*(4)=0, the matrix is converted to the upper part of the matrix *A* in the CSR format.

If *job*(4)=1, the matrix is converted to the lower part of the matrix *A* in the CSR format.

job(5)

job(5)=*nzmax* - maximum number of the non-zero elements of the matrix *A* if *job*(1)=0.

job(6) - job indicator.

Only for conversion to the skyline format:

	<p>If $job(6)=0$, only arrays <i>pointers</i> is filled in for the output storage.</p> <p>If $job(6)=1$, all output arrays <i>asky</i> and <i>pointers</i> are filled in for the output storage.</p>
<i>m</i>	INTEGER. Dimension of the matrix <i>A</i> .
<i>acsr</i>	(input/output) DOUBLE PRECISION. Array containing non-zero elements of the matrix <i>A</i> . Its length is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	(input/output) INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i> . Its length is equal to the length of the array <i>acsr</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	(input/output) INTEGER. Array of length $m + 1$, containing indices of elements in the array <i>acsr</i> , such that $ia(I)$ is the index in the array <i>acsr</i> of the first non-zero element from the row <i>I</i> . The value of the last element $ia(m + 1)$ is equal to the number of non-zeros plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
<i>asky</i>	(input/output) DOUBLE PRECISION. Array, for a lower triangular part of <i>A</i> it contains the set of elements from each row starting from the first non-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets. Refer to <i>values</i> array description in Skyline Storage Format for more details.
<i>pointers</i>	(input/output) INTEGER. Array with dimension $(m+1)$, where <i>m</i> is number of rows for lower triangle (columns for upper triangle), $pointers(I) - pointers(1)+1$ gives the index of element in the array <i>asky</i> that is first non-zero element in row (column) <i>I</i> . The value of $pointers(m + 1)$ is set $tonnz + pointers(1)$,

where n_{nz} is the number of elements in the array *asky*. Refer to *pointers* array description in [Skyline Storage Format](#) for more details

Output Parameters

info INTEGER. Integer info indicator only for converting the matrix *A* from the CSR format.
 If *info*=0, the execution is successful.
 If *info*=1, the routine is interrupted because there is no space in the array *asky* according to the value *nzmax*.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_dcscrsky(job, m, acsr, ja, ia, asky, pointers, info)
  INTEGER      job(8)
  INTEGER      m, info
  INTEGER      ja(*), ia(m+1), pointers(m+1)
  DOUBLE PRECISION  acsr(*), asky(*)
```

C:

```
void mkl_dcscrsky(int *job, int *m, , double *acsr, int *ja,
  int *ia, double *asky, int *pointers, int *info);
```

mkl_?csradd

Computes the sum of two matrices stored in the CSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_scsradd(trans, request, sort, m, n, a, ja, ia, beta, b, jb, ib, c,
  jc, ic, nzmax, info)
```

```
call mkl_dcsradd(trans, request, sort, m, n, a, ja, ia, beta, b, jb, ib, c,  
jc, ic, nzmax, info)
```

```
call mkl_ccsradd(trans, request, sort, m, n, a, ja, ia, beta, b, jb, ib, c,  
jc, ic, nzmax, info)
```

```
call mkl_zcsradd(trans, request, sort, m, n, a, ja, ia, beta, b, jb, ib, c,  
jc, ic, nzmax, info)
```

C:

```
mkl_scsradd(&trans, &request, &sort, &m, &n, a, ja, ia, &beta, b, jb, ib, c,  
jc, ic, &nzmax, &info);
```

```
mkl_dcsradd(&trans, &request, &sort, &m, &n, a, ja, ia, &beta, b, jb, ib, c,  
jc, ic, &nzmax, &info);
```

```
mkl_ccsradd(&trans, &request, &sort, &m, &n, a, ja, ia, &beta, b, jb, ib, c,  
jc, ic, &nzmax, &info);
```

```
mkl_zcsradd(&trans, &request, &sort, &m, &n, a, ja, ia, &beta, b, jb, ib, c,  
jc, ic, &nzmax, &info);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?csradd` routine performs a matrix-matrix operation defined as

$$C := A + \beta \text{op}(B)$$

where:

A , B , C are the sparse matrices in the CSR format (3-array variation).

$\text{op}(B)$ is one of $\text{op}(B) = B$, or $\text{op}(B) = B'$, or $\text{op}(A) = \text{conjg}(B')$

β is a scalar.

The routine works correctly if and only if the column indices in sparse matrix representations of matrices A and B are arranged in the increasing order for each row. If not, use the parameter `sort` (see below) to reorder column indices and the corresponding elements of the input matrices.

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>trans</i>	<p>CHARACTER*1. Specifies the operation. If <i>trans</i> = 'N' or 'n', then $C := A + \beta B$ If <i>trans</i> = 'T' or 't' or 'C' or 'c', then $C := A + \beta B'$.</p>
<i>request</i>	<p>INTEGER. If <i>request</i>=0, the routine performs addition, the memory for the output arrays <i>ic</i>, <i>jc</i>, <i>c</i> must be allocated beforehand. If <i>request</i>=1, the routine computes only values of the array <i>ic</i> of length $m + 1$, the memory for this array must be allocated beforehand. On exit the value $ic(m+1) - 1$ is the actual number of the elements in the arrays <i>c</i> and <i>jc</i>. If <i>request</i>=2, the routine has been called previously with the parameter <i>request</i>=1, the output arrays <i>jc</i> and <i>c</i> are allocated in the calling program and they are of the length $(m+1) - 1$ at least.</p>
<i>sort</i>	<p>INTEGER. Specifies the type of reordering. If this parameter is not set (default), the routine does not perform reordering. If <i>sort</i>=1, the routine arranges the column indices <i>ja</i> for each row in the increasing order and reorders the corresponding values of the matrix <i>A</i> in the array <i>a</i>. If <i>sort</i>=2, the routine arranges the column indices <i>jb</i> for each row in the increasing order and reorders the corresponding values of the matrix <i>B</i> in the array <i>b</i>. If <i>sort</i>=3, the routine performs reordering for both input matrices <i>A</i> and <i>B</i>.</p>
<i>m</i>	INTEGER. Number of rows of the matrix <i>A</i> .
<i>n</i>	INTEGER. Number of columns of the matrix <i>A</i> .
<i>a</i>	<p>REAL for mkl_scsradd. DOUBLE PRECISION for mkl_dcsradd. COMPLEX for mkl_ccsradd. DOUBLE COMPLEX for mkl_zcsradd.</p>

	Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>ja</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix A . For each row the column indices must be arranged in the increasing order. The length of this array is equal to the length of the array <i>a</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>ia</i>	INTEGER. Array of length $m + 1$, containing indices of elements in the array <i>a</i> , such that $ia(I)$ is the index in the array <i>a</i> of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ is equal to the number of non-zero elements of the matrix B plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.
<i>beta</i>	REAL for mkl_scsradd. DOUBLE PRECISION for mkl_dcsradd. COMPLEX for mkl_ccsradd. DOUBLE COMPLEX for mkl_zcsradd. Specifies the scalar <i>beta</i> .
<i>b</i>	REAL for mkl_scsradd. DOUBLE PRECISION for mkl_dcsradd. COMPLEX for mkl_ccsradd. DOUBLE COMPLEX for mkl_zcsradd. Array containing non-zero elements of the matrix B . Its length is equal to the number of non-zero elements in the matrix B . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.
<i>jb</i>	INTEGER. Array containing the column indices for each non-zero element of the matrix B . For each row the column indices must be arranged in the increasing order. The length of this array is equal to the length of the array <i>b</i> . Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.
<i>ib</i>	INTEGER. Array of length $m + 1$ when <i>trans</i> = 'N' or 'n', or $n + 1$ otherwise.

This array contains indices of elements in the array b , such that $ib(I)$ is the index in the array b of the first non-zero element from the row I . The value of the last element $ib(m + 1)$ or $ib(n + 1)$ is equal to the number of non-zero elements of the matrix B plus one. Refer to `rowIndex` array description in [Sparse Matrix Storage Formats](#) for more details.

`nzmax` INTEGER. The length of the arrays c and jc . This parameter is used only if `request=0`. The routine stops calculation if the number of elements in the result matrix C exceeds the specified value of `nzmax`.

Output Parameters

`c` REAL for `mkl_scsradd`.
 DOUBLE PRECISION for `mkl_dcsradd`.
 COMPLEX for `mkl_ccsradd`.
 DOUBLE COMPLEX for `mkl_zcsradd`.
 Array containing non-zero elements of the result matrix C . Its length is equal to the number of non-zero elements in the matrix C . Refer to `values` array description in [Sparse Matrix Storage Formats](#) for more details.

`jc` INTEGER. Array containing the column indices for each non-zero element of the matrix C . The length of this array is equal to the length of the array c . Refer to `columns` array description in [Sparse Matrix Storage Formats](#) for more details.

`ic` INTEGER. Array of length $m + 1$, containing indices of elements in the array c , such that $ic(I)$ is the index in the array c of the first non-zero element from the row I . The value of the last element $ic(m + 1)$ is equal to the number of non-zero elements of the matrix C plus one. Refer to `rowIndex` array description in [Sparse Matrix Storage Formats](#) for more details.

`info` INTEGER.
 If `info=0`, the execution is successful.

If $info=I>0$, the routine stops calculation in the I -th row of the matrix C because number of elements in C exceeds $nzmax$.

If $info=-1$, the routine calculates only the size of the arrays C and jc and returns this value plus 1 as the last element of the array ic .

Interfaces

int *jb, int *ib, MKL_Complex16 *c, int *jc, int *ic, int *nzmax, int *info);
```

mkl_?csrmultcsr

Computes product of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing.

Syntax

Fortran:

```
call mkl_scsrmultcsr(trans, request, sort, m, n, k, a, ja, ia, b, jb, ib, c,
jc, ic, nzmax, info)
```

```
call mkl_dcsrmultcsr(trans, request, sort, m, n, k, a, ja, ia, b, jb, ib, c,
jc, ic, nzmax, info)
```

```
call mkl_ccsrmultcsr(trans, request, sort, m, n, k, a, ja, ia, b, jb, ib, c,
jc, ic, nzmax, info)
```

```
call mkl_zcsrmultcsr(trans, request, sort, m, n, k, a, ja, ia, b, jb, ib, c,
jc, ic, nzmax, info)
```

C:

```
mkl_scsrmultcsr(&trans, &request, &sort, &m, &n, &k, a, ja, ia, b, jb, ib,
c, jc, ic, &nzmax, &info);
```

```
mkl_dcsrmultcsr(&trans, &request, &sort, &m, &n, &k, a, ja, ia, b, jb, ib,
c, jc, ic, &nzmax, &info);
```

```
mkl_ccsrmultcsr(&trans, &request, &sort, &m, &n, &k, a, ja, ia, b, jb, ib,
c, jc, ic, &nzmax, &info);
```

```
mkl_zcsrmultcsr(&trans, &request, &sort, &m, &n, &k, a, ja, ia, b, jb, ib,
c, jc, ic, &nzmax, &info);
```

Description

This routine is declared in `mkl_spblas.fi` for FORTRAN 77 interface and in `mkl_spblas.h` for C interface.

The `mkl_?csrmultcsr` routine performs a matrix-matrix operation defined as

$$C := \text{op}(A) * B$$

where:

A, B, C are the sparse matrices in the CSR format (3-array variation);

$\text{op}(A)$ is one of $\text{op}(A) = A$, or $\text{op}(A) = A'$, or $\text{op}(A) = \text{conjg}(A')$.

The routine works correctly if and only if the column indices in sparse matrix representations of matrices A and B are arranged in the increasing order for each row. If not, use the parameter `sort` (see below) to reorder column indices and the corresponding elements of the input matrices.

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

<i>trans</i>	CHARACTER*1. Specifies the operation. If <i>trans</i> = 'N' or 'n', then $C := A * B$ If <i>trans</i> = 'T' or 't' or 'C' or 'c', then $C := A' * B$.
<i>request</i>	INTEGER. If <i>request</i> =0, the routine performs multiplication, the memory for the output arrays <i>ic</i> , <i>jc</i> , <i>c</i> must be allocated beforehand.

If *request=1*, the routine computes only values of the array *ic* of length $m + 1$, the memory for this array must be allocated beforehand. On exit the value $ic(m+1) - 1$ is the actual number of the elements in the arrays *c* and *jc*.
 If *request=2*, the routine has been called previously with the parameter *request=1*, the output arrays *jc* and *c* are allocated in the calling program and they are of the length $ic(m+1) - 1$ at least.

sort INTEGER. Specifies the type of reordering. If this parameter is not set (default), the routine does not perform reordering. If *sort=1*, the routine arranges the column indices *ja* for each row in the increasing order and reorders the corresponding values of the matrix *A* in the array *a*. If *sort=2*, the routine arranges the column indices *jb* for each row in the increasing order and reorders the corresponding values of the matrix *B* in the array *b*. If *sort=3*, the routine performs reordering for both input matrices *A* and *B*.

m INTEGER. Number of rows of the matrix *A*.

n INTEGER. Number of columns of the matrix *A*.

k INTEGER. Number of columns of the matrix *B*.

a REAL for mkl_scsrmultcsr.
 DOUBLE PRECISION for mkl_dcsrmultcsr.
 COMPLEX for mkl_ccsrmultcsr.
 DOUBLE COMPLEX for mkl_zcsrmultcsr.
 Array containing non-zero elements of the matrix *A*. Its length is equal to the number of non-zero elements in the matrix *A*. Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

ja INTEGER. Array containing the column indices for each non-zero element of the matrix *A*. For each row the column indices must be arranged in the increasing order. The length of this array is equal to the length of the array *a*. Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ia INTEGER. Array of length $m + 1$ when *trans* = 'N' or 'n', or $n + 1$ otherwise.

This array contains indices of elements in the array a , such that $ia(I)$ is the index in the array a of the first non-zero element from the row I . The value of the last element $ia(m + 1)$ or $ia(n + 1)$ is equal to the number of non-zero elements of the matrix A plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

b	<p>REAL for <code>mkl_scsrmultcsr</code>. DOUBLE PRECISION for <code>mkl_dcscrmultcsr</code>. COMPLEX for <code>mkl_ccscrmultcsr</code>. DOUBLE COMPLEX for <code>mkl_zcscrmultcsr</code>.</p> <p>Array containing non-zero elements of the matrix B. Its length is equal to the number of non-zero elements in the matrix B. Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.</p>
jb	<p>INTEGER. Array containing the column indices for each non-zero element of the matrix B. For each row the column indices must be arranged in the increasing order. The length of this array is equal to the length of the array b. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.</p>
ib	<p>INTEGER. Array of length $m + 1$.</p> <p>This array contains indices of elements in the array b, such that $ib(I)$ is the index in the array b of the first non-zero element from the row I. The value of the last element $ib(m + 1)$ is equal to the number of non-zero elements of the matrix B plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.</p>
$nzmax$	<p>INTEGER. The length of the arrays c and jc.</p> <p>This parameter is used only if <i>request</i>=0. The routine stops calculation if the number of elements in the result matrix C exceeds the specified value of <i>nzmax</i>.</p>

Output Parameters

c	<p>REAL for <code>mkl_scsrmultcsr</code>. DOUBLE PRECISION for <code>mkl_dcscrmultcsr</code>. COMPLEX for <code>mkl_ccscrmultcsr</code>.</p>
-----	--

DOUBLE COMPLEX for `mkl_zcsrmultcsr`.
Array containing non-zero elements of the result matrix C . Its length is equal to the number of non-zero elements in the matrix C . Refer to *values* array description in [Sparse Matrix Storage Formats](#) for more details.

jc INTEGER. Array containing the column indices for each non-zero element of the matrix C . The length of this array is equal to the length of the array c . Refer to *columns* array description in [Sparse Matrix Storage Formats](#) for more details.

ic INTEGER. Array of length $m + 1$ when *trans* = 'N' or 'n', or $n + 1$ otherwise. This array contains indices of elements in the array c , such that $ic(I)$ is the index in the array c of the first non-zero element from the row I . The value of the last element $ic(m + 1)$ or $ic(n + 1)$ is equal to the number of non-zero elements of the matrix C plus one. Refer to *rowIndex* array description in [Sparse Matrix Storage Formats](#) for more details.

info INTEGER.
If *info*=0, the execution is successful.
If *info*= $I > 0$, the routine stops calculation in the I -th row of the matrix C because number of elements in C exceeds *nzmax*.
If *info*=-1, the routine calculates only the size of the arrays c and jc and returns this value plus 1 as the last element of the array ic .

MKL_Complex16 *c, int *jc, int *ic, int *nzmax, int *info);
```

mkl_?csmultd

Computes product of two sparse matrices stored in the CSR format (3-array variation) with one-based indexing. The result is stored in the dense matrix.

Syntax

Fortran:

```
call mkl_scsrmultd(trans, m, n, k, a, ja, ia, b, jb, ib, c, ldc)
call mkl_dcsmultd(trans, m, n, k, a, ja, ia, b, jb, ib, c, ldc)
call mkl_ccsmultd(trans, m, n, k, a, ja, ia, b, jb, ib, c, ldc)
call mkl_zcsmultd(trans, m, n, k, a, ja, ia, b, jb, ib, c, ldc)
```

C:

```
mkl_scsrmultd(&trans, &m, &n, &k, a, ja, ia, b, jb, ib, c, &ldc);
mkl_dcsmultd(&trans, &m, &n, &k, a, ja, ia, b, jb, ib, c, &ldc);
mkl_ccsmultd(&trans, &m, &n, &k, a, ja, ia, b, jb, ib, c, &ldc);
mkl_zcsmultd(&trans, &m, &n, &k, a, ja, ia, b, jb, ib, c, &ldc);
```

Description

This routine is declared in `mkl_splblas.fi` for FORTRAN 77 interface and in `mkl_splblas.h` for C interface.

The `mkl_?csrmultd` routine performs a matrix-matrix operation defined as

$$C := \text{op}(A)*B$$

where:

A , B are the sparse matrices in the CSR format (3-array variation), C is dense matrix;

$\text{op}(A)$ is one of $\text{op}(A) = A$, or $\text{op}(A) = A'$, or $\text{op}(A) = \text{conjg}(A')$.

The routine works correctly if and only if the column indices in sparse matrix representations of matrices A and B are arranged in the increasing order for each row. If not, use the parameter `sort` (see below) to reorder column indices and the corresponding elements of the input matrices.

NOTE. This routine supports only one-based indexing of the input arrays.

Input Parameters

Parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

<i>trans</i>	CHARACTER*1. Specifies the operation. If <i>trans</i> = 'N' or 'n', then $C := A*B$ If <i>trans</i> = 'T' or 't' or 'C' or 'c', then $C := A'*B$.
<i>m</i>	INTEGER. Number of rows of the matrix A .
<i>n</i>	INTEGER. Number of columns of the matrix A .
<i>k</i>	INTEGER. Number of columns of the matrix B .
<i>a</i>	REAL for <code>mkl_scsrmultd</code> . DOUBLE PRECISION for <code>mkl_dcsrmultd</code> . COMPLEX for <code>mkl_ccsrmultd</code> . DOUBLE COMPLEX for <code>mkl_zcsrmultd</code> . Array containing non-zero elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.

<i>ja</i>	<p>INTEGER. Array containing the column indices for each non-zero element of the matrix <i>A</i>. For each row the column indices must be arranged in the increasing order. The length of this array is equal to the length of the array <i>a</i>. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.</p>
<i>ia</i>	<p>INTEGER. Array of length $m + 1$ when <i>trans</i> = 'N' or 'n', or $n + 1$ otherwise. This array contains indices of elements in the array <i>a</i>, such that <i>ia</i>(<i>I</i>) is the index in the array <i>a</i> of the first non-zero element from the row <i>I</i>. The value of the last element <i>ia</i>($m + 1$) or <i>ia</i>($n + 1$) is equal to the number of non-zero elements of the matrix <i>A</i> plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.</p>
<i>b</i>	<p>REAL for mkl_scsrultd. DOUBLE PRECISION for mkl_dcscrultd. COMPLEX for mkl_ccscrultd. DOUBLE COMPLEX for mkl_zcscrultd.</p> <p>Array containing non-zero elements of the matrix <i>B</i>. Its length is equal to the number of non-zero elements in the matrix <i>B</i>. Refer to <i>values</i> array description in Sparse Matrix Storage Formats for more details.</p>
<i>jb</i>	<p>INTEGER. Array containing the column indices for each non-zero element of the matrix <i>B</i>. For each row the column indices must be arranged in the increasing order. The length of this array is equal to the length of the array <i>b</i>. Refer to <i>columns</i> array description in Sparse Matrix Storage Formats for more details.</p>
<i>ib</i>	<p>INTEGER. Array of length $m + 1$. This array contains indices of elements in the array <i>b</i>, such that <i>ib</i>(<i>I</i>) is the index in the array <i>b</i> of the first non-zero element from the row <i>I</i>. The value of the last element <i>ib</i>($m + 1$) is equal to the number of non-zero elements of the matrix <i>B</i> plus one. Refer to <i>rowIndex</i> array description in Sparse Matrix Storage Formats for more details.</p>

Output Parameters

<i>c</i>	REAL for mkl_scsrmultd. DOUBLE PRECISION for mkl_dcscrmultd. COMPLEX for mkl_ccscrmultd. DOUBLE COMPLEX for mkl_zcscrmultd. Array containing non-zero elements of the result matrix <i>c</i> .
<i>ldc</i>	INTEGER. Specifies the first dimension of the dense matrix <i>c</i> as declared in the calling (sub)program. Must be at least $\max(m, 1)$ when <i>trans</i> = 'N' or 'n', or $\max(1, n)$ otherwise.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_scsrmultd( trans, m, n, k, a, ja, ia, b, jb, ib, c, ldc)
    CHARACTER*1  trans
    INTEGER      m, n, k, ldc
    INTEGER      ja(*), jb(*), ia(*), ib(*)

MKL_Complex16 *c, int *ldc);

```

BLAS-like Extensions

Intel MKL provides C and Fortran routines to perform certain data manipulation, including matrix in-place and out-of-place transposition operations combined with simple matrix arithmetic operations. Transposition operations are Copy As Is, Conjugate transpose, Transpose, and Conjugate. Each routine adds the possibility of scaling during the transposition operation by giving some *alpha* and/or *beta* parameters. Each routine supports both row-major orderings and column-major orderings.

There is also `?gemm3m`, a routine that computes a matrix-matrix product of general complex matrices using matrix multiplication.

Table 2-10 lists these routines.

The `<?>` symbol in the routine short names is a precision prefix that indicates the data type:

<i>s</i>	REAL for Fortran interface, or <code>float</code> for C interface
<i>d</i>	DOUBLE PRECISION for Fortran interface, or <code>double</code> for C interface.
<i>c</i>	COMPLEX for Fortran interface, or <code>MKL_Complex8</code> for C interface.
<i>z</i>	DOUBLE COMPLEX for Fortran interface, or <code>MKL_Complex16</code> for C interface.

Table 2-10. BLAS-like Extensions

Routine	Data Types	Description
<code>mkl_?imatcopy</code>	<i>s, d, c, z</i>	Performs scaling and in-place transposition/copying of matrices.
<code>mkl_?omatcopy</code>	<i>s, d, c, z</i>	Performs scaling and out-of-place transposition/copying of matrices.

Routine	Data Types	Description
mkl_?omatcopy2	s, d, c, z	Performs two-strided scaling and out-of-place transposition/copying of matrices.
mkl_?omatadd	s, d, c, z	Performs scaling and sum of two matrices including their out-of-place transposition/copying.
?gemm3m	c, z	Computes a scalar-matrix-matrix product using matrix multiplications and adds the result to a scalar-matrix product.

[mkl_?imatcopy](#)

Performs scaling and in-place transposition/copying of matrices.

Syntax

Fortran:

```
call mkl_simatcopy(ordering, trans, rows, cols, alpha, a, src_lda, dst_lda)
call mkl_dimatcopy(ordering, trans, rows, cols, alpha, a, src_lda, dst_lda)
call mkl_cimatcopy(ordering, trans, rows, cols, alpha, a, src_lda, dst_lda)
call mkl_zimatcopy(ordering, trans, rows, cols, alpha, a, src_lda, dst_lda)
```

C:

```
mkl_simatcopy(ordering, trans, rows, cols, alpha, a, src_lda, dst_lda);
mkl_dimatcopy(ordering, trans, rows, cols, alpha, a, src_lda, dst_lda);
mkl_cimatcopy(ordering, trans, rows, cols, alpha, a, src_lda, dst_lda);
mkl_zimatcopy(ordering, trans, rows, cols, alpha, a, src_lda, dst_lda);
```

Description

This routine is declared in `mkl_trans.fi` for FORTRAN 77 interface and in `mkl_trans.h` for C interface. Always reference `mkl_trans.h` for C interface correct resolution.

The `mkl_?imatcopy` routine performs scaling and in-place transposition/copying of matrices. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The operation is defined as follows:

$$A := \alpha * \text{op}(A).$$

The routine parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section "**Interfaces**" below.

Note that different arrays should not overlap.

Input Parameters

<i>ordering</i>	CHARACTER*1. Ordering of the matrix storage. If <i>ordering</i> = 'R' or 'r', the ordering is row-major. If <i>ordering</i> = 'C' or 'c', the ordering is column-major.
<i>trans</i>	CHARACTER*1. Parameter that specifies the operation type. If <i>trans</i> = 'N' or 'n', $\text{op}(A)=A$ and the matrix <i>A</i> is assumed unchanged on input. If <i>trans</i> = 'T' or 't', it is assumed that <i>A</i> should be transposed. If <i>trans</i> = 'C' or 'c', it is assumed that <i>A</i> should be conjugate transposed. If <i>trans</i> = 'R' or 'r', it is assumed that <i>A</i> should be only conjugated. If the data is real, then <i>trans</i> = 'R' is the same as <i>trans</i> = 'N', and <i>trans</i> = 'C' is the same as <i>trans</i> = 'T'.
<i>rows</i>	INTEGER. The number of matrix rows.
<i>cols</i>	INTEGER. The number of matrix columns.
<i>a</i>	REAL for <code>mkl_simatcopy</code> . DOUBLE PRECISION for <code>mkl_dimatcopy</code> . COMPLEX for <code>mkl_cimatcopy</code> . DOUBLE COMPLEX for <code>mkl_zimatcopy</code> . Array, DIMENSION $a(\text{scr_lda}, *)$.
<i>alpha</i>	REAL for <code>mkl_simatcopy</code> . DOUBLE PRECISION for <code>mkl_dimatcopy</code> . COMPLEX for <code>mkl_cimatcopy</code> . DOUBLE COMPLEX for <code>mkl_zimatcopy</code> . This parameter scales the input matrix by <i>alpha</i> .

<i>src_lda</i>	<p>INTEGER. Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix; measured in the number of elements.</p> <p>This parameter must be at least $\max(1, rows)$ if <i>ordering</i> = 'C' or 'c', and $\max(1, cols)$ otherwise.</p>
<i>dst_lda</i>	<p>INTEGER. Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the destination matrix; measured in the number of elements.</p> <p>To determine the minimum value of <i>dst_lda</i> on output, consider the following guideline:</p> <p>If <i>ordering</i> = 'C' or 'c', then</p> <ul style="list-style-type: none">• If <i>trans</i> = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, rows)$• If <i>trans</i> = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, cols)$ <p>If <i>ordering</i> = 'R' or 'r', then</p> <ul style="list-style-type: none">• If <i>trans</i> = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, cols)$• If <i>trans</i> = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, rows)$

Output Parameters

<i>a</i>	<p>REAL for <i>mkl_simatcopy</i>. DOUBLE PRECISION for <i>mkl_dimatcopy</i>. COMPLEX for <i>mkl_cimatcopy</i>. DOUBLE COMPLEX for <i>mkl_zimatcopy</i>. Array, DIMENSION at least <i>m</i>. Contains the matrix <i>A</i>.</p>

```

C:

```
mkl_somatcopy(ordering, trans, rows, cols, alpha, SRC, src_stride, DST, dst_stride);
```

```
mkl_domatcopy(ordering, trans, rows, cols, alpha, SRC, src_stride, DST, dst_stride);
```

```
mkl_comatcopy(ordering, trans, rows, cols, alpha, SRC, src_stride, DST, dst_stride);
```

```
mkl_zomatcopy(ordering, trans, rows, cols, alpha, SRC, src_stride, DST, dst_stride);
```

Description

This routine is declared in `mkl_trans.fi` for FORTRAN 77 interface and in `mkl_trans.h` for C interface. Always reference `mkl_trans.h` for C interface correct resolution.

The `mkl_?omatcopy` routine performs scaling and out-of-place transposition/copying of matrices. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The operation is defined as follows:

$$B := \alpha * \text{op}(A)$$

The routine parameter descriptions are common for all implemented interfaces with the exception of data types that mostly refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

Note that different arrays should not overlap.

Input Parameters

<i>ordering</i>	CHARACTER*1. Ordering of the matrix storage. If <i>ordering</i> = 'R' or 'r', the ordering is row-major. If <i>ordering</i> = 'C' or 'c', the ordering is column-major.
<i>trans</i>	CHARACTER*1. Parameter that specifies the operation type. If <i>trans</i> = 'N' or 'n', $op(A)=A$ and the matrix <i>A</i> is assumed unchanged on input. If <i>trans</i> = 'T' or 't', it is assumed that <i>A</i> should be transposed. If <i>trans</i> = 'C' or 'c', it is assumed that <i>A</i> should be conjugate transposed. If <i>trans</i> = 'R' or 'r', it is assumed that <i>A</i> should be only conjugated. If the data is real, then <i>trans</i> = 'R' is the same as <i>trans</i> = 'N', and <i>trans</i> = 'C' is the same as <i>trans</i> = 'T'.
<i>rows</i>	INTEGER. The number of matrix rows.
<i>cols</i>	INTEGER. The number of matrix columns.
<i>alpha</i>	REAL for mkl_somatcopy. DOUBLE PRECISION for mkl_domatcopy. COMPLEX for mkl_comatcopy. DOUBLE COMPLEX for mkl_zomatcopy. This parameter scales the input matrix by <i>alpha</i> .
<i>src</i>	REAL for mkl_somatcopy. DOUBLE PRECISION for mkl_domatcopy. COMPLEX for mkl_comatcopy. DOUBLE COMPLEX for mkl_zomatcopy. Array, DIMENSION <i>src</i> (<i>scr_ld</i> , *).
<i>src_ld</i>	INTEGER. (Fortran interface). Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix; measured in the number of elements.

	<p>This parameter must be at least $\max(1, rows)$ if <i>ordering</i> = 'C' or 'c', and $\max(1, cols)$ otherwise.</p>
<i>src_stride</i>	<p>INTEGER. (C interface). Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix; measured in the number of elements.</p> <p>This parameter must be at least $\max(1, rows)$ if <i>ordering</i> = 'C' or 'c', and $\max(1, cols)$ otherwise.</p>
<i>dst</i>	<p>REAL for <i>mkl_somatcopy</i>. DOUBLE PRECISION for <i>mkl_domatcopy</i>. COMPLEX for <i>mkl_comatcopy</i>. DOUBLE COMPLEX for <i>mkl_zomatcopy</i>. Array, DIMENSION <i>dst(dst_ld, *)</i>.</p>
<i>dst_ld</i>	<p>INTEGER. (Fortran interface). Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the destination matrix; measured in the number of elements.</p> <p>To determine the minimum value of <i>dst_lda</i> on output, consider the following guideline: If <i>ordering</i> = 'C' or 'c', then</p> <ul style="list-style-type: none"> • If <i>trans</i> = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, rows)$ • If <i>trans</i> = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, cols)$ <p>If <i>ordering</i> = 'R' or 'r', then</p> <ul style="list-style-type: none"> • If <i>trans</i> = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, cols)$ • If <i>trans</i> = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, rows)$
<i>dst_stride</i>	<p>INTEGER. (C interface). Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the destination matrix; measured in the number of elements.</p>

To determine the minimum value of *dst_lda* on output, consider the following guideline:

If *ordering* = 'C' or 'c', then

- If *trans* = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, rows)$
- If *trans* = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, cols)$

If *ordering* = 'R' or 'r', then

- If *trans* = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, cols)$
- If *trans* = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, rows)$

Output Parameters

dst

REAL for *mkl_somatcopy*.

DOUBLE PRECISION for *mkl_domatcopy*.

COMPLEX for *mkl_comatcopy*.

DOUBLE COMPLEX for *mkl_zomatcopy*.

Array, DIMENSION at least *m*.

Contains the destination matrix.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_somatcopy ( ordering, trans, rows, cols, alpha, src, src_ld, dst, dst_ld )
  CHARACTER*1 ordering, trans
  INTEGER rows, cols, src_ld, dst_ld
  REAL alpha, dst(dst_ld,*), src(src_ld,*)

SUBROUTINE mkl_domatcopy ( ordering, trans, rows, cols, alpha, src, src_ld, dst, dst_ld )
  CHARACTER*1 ordering, trans
  INTEGER rows, cols, src_ld, dst_ld
  DOUBLE PRECISION alpha, dst(dst_ld,*), src(src_ld,*)

SUBROUTINE mkl_comatcopy ( ordering, trans, rows, cols, alpha, src, src_ld, dst, dst_ld )
  CHARACTER*1 ordering, trans
  INTEGER rows, cols, src_ld, dst_ld
  COMPLEX alpha, dst(dst_ld,*), src(src_ld,*)

SUBROUTINE mkl_zomatcopy ( ordering, trans, rows, cols, alpha, src, src_ld, dst, dst_ld )
  CHARACTER*1 ordering, trans
  INTEGER rows, cols, src_ld, dst_ld
  DOUBLE COMPLEX alpha, dst(dst_ld,*), src(src_ld,*)
```

C:

```
void mkl_somatcopy(char ordering, char trans, size_t rows, size_t cols, float *alpha, float
 *SRC, size_t src_stride, float *DST, size_t dst_stride);

void mkl_domatcopy(char ordering, char trans, size_t rows, size_t cols, float *alpha, double
 *SRC, size_t src_stride, double *DST, size_t dst_stride);

void mkl_comatcopy(char ordering, char trans, size_t rows, size_t cols, MKL_Complex8 *alpha,
 MKL_Complex8 *SRC, size_t src_stride, MKL_Complex8 *DST, size_t dst_stride);

void mkl_zomatcopy(char ordering, char trans, size_t rows, size_t cols, MKL_Complex16 *alpha,
 MKL_Complex16 *SRC, size_t src_stride, MKL_Complex16 *DST, size_t dst_stride);
```

mkl_?omatcopy2

Performs two-strided scaling and out-of-place transposition/copying of matrices.

Syntax

Fortran:

```
call mkl_somatcopy2(ordering, trans, rows, cols, alpha, src, src_row, src_col,  
dst, dst_row, dst_col)  
  
call mkl_domatcopy2(ordering, trans, rows, cols, alpha, src, src_row, src_col,  
dst, dst_row, dst_col)  
  
call mkl_comatcopy2(ordering, trans, rows, cols, alpha, src, src_row, src_col,  
dst, dst_row, dst_col)  
  
call mkl_zomatcopy2(ordering, trans, rows, cols, alpha, src, src_row, src_col,  
dst, dst_row, dst_col)
```

C:

```
mkl_somatcopy2(ordering, trans, rows, cols, alpha, SRC, src_row, src_col,  
DST, dst_row, dst_col);  
  
mkl_domatcopy2(ordering, trans, rows, cols, alpha, SRC, src_row, src_col,  
DST, dst_row, dst_col);  
  
mkl_comatcopy2(ordering, trans, rows, cols, alpha, SRC, src_row, src_col,  
DST, dst_row, dst_col);  
  
mkl_zomatcopy2(ordering, trans, rows, cols, alpha, SRC, src_row, src_col,  
DST, dst_row, dst_col);
```

Description

This routine is declared in `mkl_trans.fi` for FORTRAN 77 interface and in `mkl_trans.h` for C interface. Always reference `mkl_trans.h` for C interface correct resolution.

The `mkl_?omatcopy2` routine performs two-strided scaling and out-of-place transposition/copying of matrices. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The operation is defined as follows:

$$B := \alpha * \text{op}(A)$$

Normally, matrices in the BLAS or LAPACK are specified by a single stride index. For instance, in the column-major order, $A(2,1)$ is stored in memory one element away from $A(1,1)$, but $A(1,2)$ is a leading dimension away. The leading dimension in this case is the single stride. If a matrix has two strides, then both $A(2,1)$ and $A(1,2)$ may be an arbitrary distance from $A(1,1)$.

The routine parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section “**Interfaces**” below.

Note that different arrays should not overlap.

Input Parameters

<i>ordering</i>	CHARACTER*1. Ordering of the matrix storage. If <i>ordering</i> = 'R' or 'r', the ordering is row-major. If <i>ordering</i> = 'C' or 'c', the ordering is column-major.
<i>trans</i>	CHARACTER*1. Parameter that specifies the operation type. If <i>trans</i> = 'N' or 'n', $op(A)=A$ and the matrix <i>A</i> is assumed unchanged on input. If <i>trans</i> = 'T' or 't', it is assumed that <i>A</i> should be transposed. If <i>trans</i> = 'C' or 'c', it is assumed that <i>A</i> should be conjugate transposed. If <i>trans</i> = 'R' or 'r', it is assumed that <i>A</i> should be only conjugated. If the data is real, then <i>trans</i> = 'R' is the same as <i>trans</i> = 'N', and <i>trans</i> = 'C' is the same as <i>trans</i> = 'T'.
<i>rows</i>	INTEGER. The number of matrix rows.
<i>cols</i>	INTEGER. The number of matrix columns.
<i>alpha</i>	REAL for mkl_somatcopy2. DOUBLE PRECISION for mkl_domatcopy2. COMPLEX for mkl_comatcopy2. DOUBLE COMPLEX for mkl_zomatcopy2. This parameter scales the input matrix by <i>alpha</i> .
<i>src</i>	REAL for mkl_somatcopy2. DOUBLE PRECISION for mkl_domatcopy2. COMPLEX for mkl_comatcopy2. DOUBLE COMPLEX for mkl_zomatcopy2. Array, DIMENSION <i>src</i> (*).

<i>src_row</i>	<p>INTEGER. Distance between the first elements in adjacent rows in the source matrix; measured in the number of elements.</p> <p>This parameter must be at least $\max(1, rows)$.</p>
<i>src_col</i>	<p>INTEGER. Distance between the first elements in adjacent columns in the source matrix; measured in the number of elements.</p> <p>This parameter must be at least $\max(1, cols)$.</p>
<i>dst</i>	<p>REAL for <code>mkl_somatcopy2</code>. DOUBLE PRECISION for <code>mkl_domatcopy2</code>. COMPLEX for <code>mkl_comatcopy2</code>. DOUBLE COMPLEX for <code>mkl_zomatcopy2</code>. Array, DIMENSION <i>dst</i>(*).</p>
<i>dst_row</i>	<p>INTEGER. Distance between the first elements in adjacent rows in the destination matrix; measured in the number of elements.</p> <p>To determine the minimum value of <i>dst_row</i> on output, consider the following guideline:</p> <ul style="list-style-type: none"> • If <i>trans</i> = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, cols)$ • If <i>trans</i> = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, rows)$
<i>dst_col</i>	<p>INTEGER. Distance between the first elements in adjacent columns in the destination matrix; measured in the number of elements.</p> <p>To determine the minimum value of <i>dst_lda</i> on output, consider the following guideline:</p> <ul style="list-style-type: none"> • If <i>trans</i> = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, rows)$ • If <i>trans</i> = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, cols)$

Output Parameters

dst REAL for `mkl_somatcopy2`.

DOUBLE PRECISION for mkl_domatcopy2.
COMPLEX for mkl_comatcopy2.
DOUBLE COMPLEX for mkl_zomatcopy2.
Array, DIMENSION at least *m*.
Contains the destination matrix.

Interfaces

FORTRAN 77:

```
SUBROUTINE mkl_somatcopy2 ( ordering, trans, rows, cols, alpha, src, src_row, src_col, dst,
  dst_row, dst_col )
  CHARACTER*1 ordering, trans

  INTEGER rows, cols, src_row, src_col, dst_row, dst_col
  DOUBLE COMPLEX alpha, dst(*), src(*)
```

C:

```
void mkl_somatcopy2(char ordering, char trans, size_t rows, size_t cols, float *alpha, float
 *SRC, size_t src_row, size_t src_col, float *DST, size_t dst_row, size_t dst_col);

void mkl_domatcopy2(char ordering, char trans, size_t rows, size_t cols, float *alpha,
 double *SRC, size_t src_row, size_t src_col, double *DST, size_t dst_row, size_t dst_col);

void mkl_comatcopy2(char ordering, char trans, size_t rows, size_t cols, MKL_Complex8 *alpha,
 MKL_Complex8 *SRC, size_t src_row, size_t src_col, MKL_Complex8 *DST, size_t dst_row,
 size_t dst_col);

void mkl_zomatcopy2(char ordering, char trans, size_t rows, size_t cols, MKL_Complex16
 *alpha, MKL_Complex16 *SRC, size_t src_row, size_t src_col, MKL_Complex16 *DST, size_t
 dst_row, size_t dst_col);
```

mkl_?omatadd

Performs scaling and sum of two matrices including their out-of-place transposition/copying.

Syntax**Fortran:**

```
call mkl_somatadd(ordering, transa, transb, m, n, alpha, a, lda, beta, b,
 ldb, c, ldc)

call mkl_domatadd(ordering, transa, transb, m, n, alpha, a, lda, beta, b,
 ldb, c, ldc)

call mkl_comatadd(ordering, transa, transb, m, n, alpha, a, lda, beta, b,
 ldb, c, ldc)

call mkl_zomatadd(ordering, transa, transb, m, n, alpha, a, lda, beta, b,
 ldb, c, ldc)
```

C:

```
mkl_somatadd(ordering, transa, transb, m, n, alpha, A, lda, beta, B, ldb, C,
 ldc);

mkl_domatadd(ordering, transa, transb, m, n, alpha, A, lda, beta, B, ldb, C,
 ldc);

mkl_comatadd(ordering, transa, transb, m, n, alpha, A, lda, beta, B, ldb, C,
 ldc);
```

```
mkl_zomatadd(ordering, transa, transb, m, n, alpha, A, lda, beta, B, ldb, C,  
ldc);
```

Description

This routine is declared in `mkl_trans.fi` for FORTRAN 77 interface and in `mkl_trans.h` for C interface. Always reference `mkl_trans.h` for C interface correct resolution.

The `mkl_?omatadd` routine scaling and sum of two matrices including their out-of-place transposition/copying. A transposition operation can be a normal matrix copy, a transposition, a conjugate transposition, or just a conjugation. The following out-of-place memory movement is done:

$$C := \alpha * \text{op}(A) + \beta * \text{op}(B)$$

`op(A)` is either transpose, conjugate-transpose, or leave alone depending on `transa`. If no transposition of the source matrices is required, `m` is the number of rows and `n` is the number of columns in the source matrices `A` and `B`. In this case, the output matrix `C` is `m-by-n`.

The routine parameter descriptions are common for all implemented interfaces with the exception of data types that refer here to the FORTRAN 77 standard types. Data types specific to the different interfaces are described in the section **"Interfaces"** below.

Note that different arrays should not overlap.

Input Parameters

<i>ordering</i>	CHARACTER*1. Ordering of the matrix storage. If <i>ordering</i> = 'R' or 'r', the ordering is row-major. If <i>ordering</i> = 'C' or 'c', the ordering is column-major.
<i>transa</i>	CHARACTER*1. Parameter that specifies the operation type on matrix <i>A</i> . If <i>transa</i> = 'N' or 'n', <code>op(A)=A</code> and the matrix <i>A</i> is assumed unchanged on input. If <i>transa</i> = 'T' or 't', it is assumed that <i>A</i> should be transposed. If <i>transa</i> = 'C' or 'c', it is assumed that <i>A</i> should be conjugate transposed. If <i>transa</i> = 'R' or 'r', it is assumed that <i>A</i> should be only conjugated. If the data is real, then <i>transa</i> = 'R' is the same as <i>transa</i> = 'N', and <i>transa</i> = 'C' is the same as <i>transa</i> = 'T'.

<i>transb</i>	<p>CHARACTER*1. Parameter that specifies the operation type on matrix <i>B</i>.</p> <p>If <i>transb</i> = 'N' or 'n', $op(B)=B$ and the matrix <i>B</i> is assumed unchanged on input.</p> <p>If <i>transb</i> = 'T' or 't', it is assumed that <i>B</i> should be transposed.</p> <p>If <i>transb</i> = 'C' or 'c', it is assumed that <i>B</i> should be conjugate transposed.</p> <p>If <i>transb</i> = 'R' or 'r', it is assumed that <i>B</i> should be only conjugated.</p> <p>If the data is real, then <i>transb</i> = 'R' is the same as <i>transb</i> = 'N', and <i>transb</i> = 'C' is the same as <i>transb</i> = 'T'.</p>
<i>m</i>	INTEGER. The number of matrix rows.
<i>n</i>	INTEGER. The number of matrix columns.
<i>alpha</i>	<p>REAL for mkl_somatadd.</p> <p>DOUBLE PRECISION for mkl_domatadd.</p> <p>COMPLEX for mkl_comatadd.</p> <p>DOUBLE COMPLEX for mkl_zomatadd.</p> <p>This parameter scales the input matrix by <i>alpha</i>.</p>
<i>a</i>	<p>REAL for mkl_somatadd.</p> <p>DOUBLE PRECISION for mkl_domatadd.</p> <p>COMPLEX for mkl_comatadd.</p> <p>DOUBLE COMPLEX for mkl_zomatadd.</p> <p>Array, DIMENSION $a(lda, *)$.</p>
<i>lda</i>	<p>INTEGER. Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix <i>A</i>; measured in the number of elements.</p> <p>This parameter must be at least $\max(1, rows)$ if <i>ordering</i> = 'C' or 'c', and $\max(1, cols)$ otherwise.</p>
<i>beta</i>	<p>REAL for mkl_somatadd.</p> <p>DOUBLE PRECISION for mkl_domatadd.</p> <p>COMPLEX for mkl_comatadd.</p> <p>DOUBLE COMPLEX for mkl_zomatadd.</p> <p>This parameter scales the input matrix by <i>beta</i>.</p>
<i>b</i>	<p>REAL for mkl_somatadd.</p> <p>DOUBLE PRECISION for mkl_domatadd.</p>

COMPLEX for `mkl_comatadd`.
 DOUBLE COMPLEX for `mkl_zomatadd`.
 Array, DIMENSION $b(ldb, *)$.
ldb INTEGER. Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the source matrix *B*; measured in the number of elements.
 This parameter must be at least $\max(1, rows)$ if *ordering* = 'C' or 'c', and $\max(1, cols)$ otherwise.

Output Parameters

c REAL for `mkl_somatadd`.
 DOUBLE PRECISION for `mkl_domatadd`.
 COMPLEX for `mkl_comatadd`.
 DOUBLE COMPLEX for `mkl_zomatadd`.
 Array, DIMENSION $c ldc, *$.
ldc INTEGER. Distance between the first elements in adjacent columns (in the case of the column-major order) or rows (in the case of the row-major order) in the destination matrix *C*; measured in the number of elements.
 To determine the minimum value of *ldc*, consider the following guideline:
 If *ordering* = 'C' or 'c', then

- If *transa* or *transb* = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, rows)$
- If *transa* or *transb* = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, cols)$

If *ordering* = 'R' or 'r', then

- If *transa* or *transb* = 'T' or 't' or 'C' or 'c', this parameter must be at least $\max(1, cols)$
- If *transa* or *transb* = 'N' or 'n' or 'R' or 'r', this parameter must be at least $\max(1, rows)$

Interfaces

```

?gemm3m

Computes a scalar-matrix-matrix product using matrix multiplications and adds the result to a scalar-matrix product.

Syntax

FORTRAN 77:

```
call cgemm3m(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
call zgemm3m(transa, transb, m, n, k, alpha, a, lda, b, ldb, beta, c, ldc)
```

Fortran 95:

```
call gemm3m(a, b, c [,transa][,transb] [,alpha][,beta])
```

Description

This routine is declared in `mkl_blas.fi` for FORTRAN 77 interface, in `blas.f90` for Fortran 95 interface, and in `mkl_blas.h` for C interface.

The `?gemm3m` routines perform a matrix-matrix operation with general complex matrices. These routines are similar to the `?gemm` routines, but they use matrix multiplications (see *Application Notes* below).

The operation is defined as

$$C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C,$$

where:

$\text{op}(x)$ is one of $\text{op}(x) = x$, or $\text{op}(x) = x'$, or $\text{op}(x) = \text{conjg}(x')$,

α and β are scalars,

A , B and C are matrices:

$\text{op}(A)$ is an m -by- k matrix,

$\text{op}(B)$ is a k -by- n matrix,

C is an m -by- n matrix.

Input Parameters

transa CHARACTER*1. Specifies the form of $\text{op}(A)$ used in the matrix multiplication:

	<p>if <i>transa</i> = 'N' or 'n', then $\text{op}(A) = A$; if <i>transa</i> = 'T' or 't', then $\text{op}(A) = A'$; if <i>transa</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A')$.</p>
<i>transb</i>	<p>CHARACTER*1. Specifies the form of $\text{op}(B)$ used in the matrix multiplication: if <i>transb</i> = 'N' or 'n', then $\text{op}(B) = B$; if <i>transb</i> = 'T' or 't', then $\text{op}(B) = B'$; if <i>transb</i> = 'C' or 'c', then $\text{op}(B) = \text{conjg}(B')$.</p>
<i>m</i>	<p>INTEGER. Specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix <i>C</i>. The value of <i>m</i> must be at least zero.</p>
<i>n</i>	<p>INTEGER. Specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix <i>C</i>. The value of <i>n</i> must be at least zero.</p>
<i>k</i>	<p>INTEGER. Specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. The value of <i>k</i> must be at least zero.</p>
<i>alpha</i>	<p>COMPLEX for <i>cgemm3m</i> DOUBLE COMPLEX for <i>zgemm3m</i> Specifies the scalar <i>alpha</i>.</p>
<i>a</i>	<p>COMPLEX for <i>cgemm3m</i> DOUBLE COMPLEX for <i>zgemm3m</i> Array, DIMENSION (<i>lda</i>, <i>ka</i>), where <i>ka</i> is <i>k</i> when <i>transa</i> = 'N' or 'n', and is <i>m</i> otherwise. Before entry with <i>transa</i> = 'N' or 'n', the leading <i>m</i>-by-<i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i>, otherwise the leading <i>k</i>-by-<i>m</i> part of the array <i>a</i> must contain the matrix <i>A</i>.</p>
<i>lda</i>	<p>INTEGER. Specifies the first dimension of <i>a</i> as declared in the calling (sub)program. When <i>transa</i> = 'N' or 'n', then <i>lda</i> must be at least $\max(1, m)$, otherwise <i>lda</i> must be at least $\max(1, k)$.</p>
<i>b</i>	<p>COMPLEX for <i>cgemm3m</i> DOUBLE COMPLEX for <i>zgemm3m</i> Array, DIMENSION (<i>ldb</i>, <i>kb</i>), where <i>kb</i> is <i>n</i> when <i>transb</i> = 'N' or 'n', and is <i>k</i> otherwise. Before entry with <i>transb</i> = 'N' or 'n', the leading <i>k</i>-by-<i>n</i> part of the array <i>b</i> must contain the matrix <i>B</i>, otherwise the leading <i>n</i>-by-<i>k</i> part of the array <i>b</i> must contain the matrix <i>B</i>.</p>

<i>ldb</i>	INTEGER. Specifies the first dimension of <i>b</i> as declared in the calling (sub)program. When <i>transb</i> = 'N' or 'n', then <i>ldb</i> must be at least $\max(1, k)$, otherwise <i>ldb</i> must be at least $\max(1, n)$.
<i>beta</i>	COMPLEX for <i>cgemm3m</i> DOUBLE COMPLEX for <i>zgemm3m</i> Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <i>c</i> need not be set on input.
<i>c</i>	COMPLEX for <i>cgemm3m</i> DOUBLE COMPLEX for <i>zgemm3m</i> Array, DIMENSION (<i>ldc</i> , <i>n</i>). Before entry, the leading <i>m</i> -by- <i>n</i> part of the array <i>c</i> must contain the matrix <i>C</i> , except when <i>beta</i> is equal to zero, in which case <i>c</i> need not be set on entry.
<i>ldc</i>	INTEGER. Specifies the first dimension of <i>c</i> as declared in the calling (sub)program. The value of <i>ldc</i> must be at least $\max(1, m)$.

Output Parameters

<i>c</i>	Overwritten by the <i>m</i> -by- <i>n</i> matrix (<i>alpha</i> *op(<i>A</i>)*op(<i>B</i>) + <i>beta</i> * <i>C</i>).
----------	--

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gemm3m* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>ma</i> , <i>ka</i>) where <i>ka</i> = <i>k</i> if <i>transa</i> = 'N', <i>ka</i> = <i>m</i> otherwise, <i>ma</i> = <i>m</i> if <i>transa</i> = 'N', <i>ma</i> = <i>k</i> otherwise.
<i>b</i>	Holds the matrix <i>B</i> of size (<i>mb</i> , <i>kb</i>) where <i>kb</i> = <i>n</i> if <i>transb</i> = 'N', <i>kb</i> = <i>k</i> otherwise, <i>mb</i> = <i>k</i> if <i>transb</i> = 'N',

	$mb = n$ otherwise.
c	Holds the matrix C of size (m,n) .
$transa$	Must be 'N', 'C', or 'T'. The default value is 'N'.
$transb$	Must be 'N', 'C', or 'T'. The default value is 'N'.
$alpha$	The default value is 1.
$beta$	The default value is 1.

Application Notes

These routines perform the complex multiplication by forming the real and imaginary parts of the input matrices. It allows to use three real matrix multiplications and five real matrix additions, instead of the conventional four real matrix multiplications and two real matrix additions. The use of three real matrix multiplications only gives a 25% reduction of time in matrix operations. This can result in significant savings in computing time for large matrices.

If the errors in the floating point calculations satisfy the following conditions:

$$fl(x \text{ op } y) = (x \text{ op } y)(1 + \delta), \quad |\delta| \leq u, \quad \text{op} = \times, /, \quad fl(x \pm y) = x(1 + \alpha) \pm y(1 + \beta), \quad |\alpha|, |\beta| \leq u$$

then for n -by- n matrix $C = fl(C_1 + iC_2) = fl((A_1 + iA_2)(B_1 + iB_2)) = C_1 + iC_2$ the following estimations are correct

$$\|C_1 - C_2\| \leq 2(n+1)u \|A\|_\infty \|B\|_\infty + O(u^2),$$

$$\|C_2 - C_1\| \leq 4(n+4)u \|A\|_\infty \|B\|_\infty + O(u^2),$$

where $\|A\|_\infty = \max(\|A_1\|_\infty, \|A_2\|_\infty)$, and $\|B\|_\infty = \max(\|B_1\|_\infty, \|B_2\|_\infty)$.

and hence the matrix multiplications are stable.

LAPACK Routines: Linear Equations

3

This chapter describes the Intel® Math Kernel Library implementation of routines from the LAPACK package that are used for solving systems of linear equations and performing a number of related computational tasks. The library includes LAPACK routines for both real and complex data. Routines are supported for systems of equations with the following types of matrices:

- general
- banded
- symmetric or Hermitian positive-definite (full, packed, and rectangular full packed (RFP) storage)
- symmetric or Hermitian positive-definite banded
- symmetric or Hermitian indefinite (both full and packed storage)
- symmetric or Hermitian indefinite banded
- triangular (full, packed, and RFP storage)
- triangular banded
- tridiagonal
- diagonally dominant tridiagonal.

For each of the above matrix types, the library includes routines for performing the following computations:

- factoring the matrix (except for triangular matrices)
- equilibrating the matrix (except for RFP matrices)
- solving a system of linear equations
- estimating the condition number of a matrix (except for RFP matrices)
- refining the solution of linear equations and computing its error bounds (except for RFP matrices)
- inverting the matrix.

To solve a particular problem, you can call two or more [computational routines](#) or call a corresponding [driver routine](#) that combines several tasks in one call. For example, to solve a system of linear equations with a general matrix, call `?getrf` (*LU* factorization) and then `?getrs` (computing the solution). Then, call `?gerfs` to refine the solution and get the error bounds. Alternatively, use the driver routine `?gesvx` that performs all these tasks in one call.

WARNING. LAPACK routines assume that input matrices do not contain IEEE 754 special values such as `INF` or `NaN` values. Using these special values may cause LAPACK to return unexpected results or become unstable.

Starting from release 8.0, Intel MKL along with FORTRAN 77 interface to LAPACK computational and driver routines also supports Fortran 95 interface which uses simplified routine calls with shorter argument lists. The syntax section of the routine description gives the calling sequence for Fortran 95 interface, where available, immediately after FORTRAN 77 calls.

Routine Naming Conventions

To call each routine introduced in this chapter from the FORTRAN 77 program, you can use the LAPACK name.

LAPACK names are listed in [Table 3-1](#) and [Table 3-2](#), and have the structure `?yyzzz` or `?yyzz`, which is described below.

The initial symbol `?` indicates the data type:

<code>s</code>	real, single precision
<code>c</code>	complex, single precision
<code>d</code>	real, double precision
<code>z</code>	complex, double precision

Some routines can have combined character codes, such as `ds` or `zc`.

The second and third letters `yy` indicate the matrix type and storage scheme:

<code>ge</code>	general
<code>gb</code>	general band
<code>gt</code>	general tridiagonal
<code>dt</code>	diagonally dominant tridiagonal
<code>po</code>	symmetric or Hermitian positive-definite
<code>pp</code>	symmetric or Hermitian positive-definite (packed storage)
<code>pf</code>	symmetric or Hermitian positive-definite (RFP storage)
<code>pb</code>	symmetric or Hermitian positive-definite band
<code>pt</code>	symmetric or Hermitian positive-definite tridiagonal
<code>sy</code>	symmetric indefinite
<code>sp</code>	symmetric indefinite (packed storage)
<code>he</code>	Hermitian indefinite
<code>hp</code>	Hermitian indefinite (packed storage)
<code>tr</code>	triangular
<code>tp</code>	triangular (packed storage)
<code>tf</code>	triangular (RFP storage)

tb	triangular band
The last three letters <i>zzz</i> indicate the computation performed:	
trf	perform a triangular matrix factorization
trs	solve the linear system with a factored matrix
con	estimate the matrix condition number
rfs	refine the solution and compute error bounds
rfsx	refine the solution and compute error bounds using extra-precise iterative refinement
tri	compute the inverse matrix using the factorization
equ, equb	equilibrate a matrix.

For example, the `sgetrf` routine performs the triangular factorization of general real matrices in single precision; the corresponding routine for complex matrices is `cgetrf`.

Driver routine names can end with `-sv` (meaning a *simple* driver), or with `-svx` (meaning an *expert* driver) or with `-svxx` (meaning an extra-precise iterative refinement *expert* driver).

Fortran 95 interfaces to the LAPACK computational and driver routines are the same as the FORTRAN 77 names but without the first letter that indicates the data type. For example, the name of the routine that performs a triangular factorization of general real matrices in Fortran 95 is `getrf`. Different data types are handled through the definition of a specific internal parameter that refers to a module block with named constants for single and double precision.

Fortran 95 Interface Conventions

Intel® MKL implements the Fortran 95 interface to LAPACK through wrappers that call respective FORTRAN 77 routines. This interface uses such Fortran 95 features as assumed-shape arrays and optional arguments to provide simplified calls to LAPACK routines with fewer arguments.

NOTE. For LAPACK, Intel MKL offers two types of Fortran 95 interfaces:

- using `mkl_lapack.fi` only through the `include 'mkl_lapack.fi'` statement. Such interfaces allow you to make use of the original LAPACK routines with all their arguments
 - using `lapack.f90` that includes improved interfaces. This file is used to generate the module files `lapack95.mod` and `f95_precision.mod`. The module files `mkl95_lapack.mod` and `mkl95_precision.mod` are also generated. See also the section “Fortran 95 interfaces and wrappers to LAPACK and BLAS” of *Intel® MKL User's Guide* for details. The module files are used to process the FORTRAN use clauses referencing the LAPACK interface: `use lapack95` (or an equivalent `use mkl95_lapack`) and `use f95_precision` (or an equivalent `use mkl95_precision`).
-

The main conventions for the Fortran 95 interface are as follows:

- The names of arguments used in Fortran 95 call are typically the same as for the respective generic (FORTRAN 77) interface. In rare cases formal argument names may be different. For instance, `select` instead of `selctg`.
- Input arguments such as array dimensions are not required in Fortran 95 and are skipped from the calling sequence. Array dimensions are reconstructed from the user data that must exactly follow the required array shape.

Another type of generic arguments that are skipped in Fortran 95 interface are arguments that represent workspace arrays (such as `work`, `rwork`, and so on). The only exception are cases when workspace arrays return significant information on output.

An argument can also be skipped if its value is completely defined by the presence or absence of another argument in the calling sequence, and the restored value is the only meaningful value for the skipped argument.

- Some generic arguments are declared as optional in Fortran 95 interface and may or may not be present in the calling sequence. An argument can be declared optional if it satisfies one of the following conditions:
 - If the argument value is completely defined by the presence or absence of another argument in the calling sequence, it can be declared as optional. The difference from the skipped argument in this case is that the optional argument can have some meaningful values that are distinct from the value reconstructed by default. For example, if some argument (like `jobz`) can take only two values and one of these values directly implies the use of another argument, then the value of `jobz` can be uniquely reconstructed from the actual presence or absence of this second argument, and `jobz` can be omitted.
 - If an input argument can take only a few possible values, it can be declared as optional. The default value of such argument is typically set as the first value in the list and all exceptions to this rule are explicitly stated in the routine description.

- If an input argument has a natural default value, it can be declared as optional. The default value of such optional argument is set to its natural default value.
- Argument *info* is declared as optional in Fortran 95 interface. If it is present in the calling sequence, the value assigned to *info* is interpreted as follows:
 - If this value is more than -1000, its meaning is the same as in FORTRAN 77 routine.
 - If this value is equal to -1000, it means that there is not enough work memory.
 - If this value is equal to -1001, incompatible arguments are present in the calling sequence.
- Optional arguments are given in square brackets in Fortran 95 call syntax.

“Fortran 95 Notes” subsection at the end of the topic describing each routine details concrete rules for reconstructing the values of omitted optional parameters.

Intel® MKL Fortran 95 Interfaces for LAPACK Routines vs. Netlib Implementation

The following list presents general digressions of the Intel MKL LAPACK95 implementation from the Netlib analog:

- The Intel MKL Fortran 95 interfaces are provided for pure procedures.
- Names of interfaces do not contain the `LA_` prefix.
- An optional array argument always has the `target` attribute.
- Functionality of the Intel MKL LAPACK95 wrapper is close to the FORTRAN 77 original implementation in the `getrf`, `gbtrf`, and `potrf` interfaces.
- If `jobz` argument value specifies presence or absence of `z` argument, then `z` is always declared as optional and `jobz` is restored depending on whether `z` is present or not. It is not always so in the Netlib version (see “Modified Netlib Interfaces” in Appendix E).
- To avoid double error checking, processing of the `info` argument is limited to checking of the allocated memory and disarranging of optional arguments.
- If an argument that is present in the list of arguments completely defines another argument, the latter is always declared as optional.

You can transform an application that uses the Netlib LAPACK interfaces to ensure its work with the Intel MKL interfaces providing that:

- a.** The application is correct, that is, unambiguous, compiler-independent, and contains no errors.
- b.** Each routine name denotes only one specific routine. If any routine name in the application coincides with a name of the original Netlib routine (for example, after removing the `LA_` prefix) but denotes a routine different from the Netlib original routine, this name should be modified through context name replacement.

You should transform your application in the following cases (see Appendix E for specific differences of individual interfaces):

- When using the Netlib routines that differ from the Intel MKL routines only by the `LA_` prefix or in the array attribute `target`. The only transformation required in this case is context name replacement. See [“Interfaces Identical to Netlib”](#) in Appendix E for details.
- When using Netlib routines that differ from the Intel MKL routines by the `LA_` prefix, the `target` array attribute, and the names of formal arguments. In the case of positional passing of arguments, no additional transformation except context name replacement is required. In the case of the keywords passing of arguments, in addition to the context name replacement the names of mismatching keywords should also be modified. See [“Interfaces with Replaced Argument Names”](#) in Appendix E for details.
- When using the Netlib routines that differ from the respective Intel MKL routines by the `LA_` prefix, the `target` array attribute, sequence of the arguments, arguments missing in Intel MKL but present in Netlib and, vice versa, present in Intel MKL but missing in Netlib. Remove the differences in the sequence and range of the arguments in process of all the transformations when you use the Netlib routines specified by this bullet and the preceding bullet. See [“Modified Netlib Interfaces”](#) in Appendix E for details.
- When using the `getrf`, `gbtrf`, and `potrf` interfaces, that is, new functionality implemented in Intel MKL but unavailable in the Netlib source. To override the differences, build the desired functionality explicitly with the Intel MKL means or create a new subroutine with the new functionality, using specific MKL interfaces corresponding to LAPACK 77 routines. You can call the LAPACK 77 routines directly but using the new Intel MKL interfaces is preferable. See [“Interfaces Absent From Netlib”](#) and [“Interfaces of New Functionality”](#) in Appendix E for details.
Note that if the transformed application calls `getrf`, `gbtrf` or `potrf` without controlling arguments `rcond` and `norm`, just context name replacement is enough in modifying the calls into the Intel MKL interfaces, as described in the first bullet above. The Netlib functionality is preserved in such cases.
- When using the Netlib auxiliary routines. In this case, call a corresponding subroutine directly, using the MKL LAPACK 77 interfaces.

Transform your application as follows:

- 1.** Make sure conditions a. and b. are met.
- 2.** Select Netlib LAPACK 95 calls. For each call do the following:
 - Select the type of digression and do the required transformations.
 - Revise results to eliminate unneeded code or data, which may appear after several identical calls.
- 3.** Make sure the transformations are correct and complete.

Matrix Storage Schemes

LAPACK routines use the following matrix storage schemes:

- *Full storage*: a matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.
- *Packed storage* scheme allows you to store symmetric, Hermitian, or triangular matrices more compactly: the upper or lower triangle of the matrix is packed by columns in a one-dimensional array.
- *Band storage*: an m -by- n band matrix with k_l sub-diagonals and k_u superdiagonals is stored compactly in a two-dimensional array ab with k_l+k_u+1 rows and n columns. Columns of the matrix are stored in the corresponding columns of the array, and *diagonals* of the matrix are stored in rows of the array.
- *Rectangular Full Packed (RFP) storage*: the upper or lower triangle of the matrix is packed combining the full and packed storage schemes. This combination enables using half of the full storage as packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels as the full storage.

In Chapters 4 and 5, arrays that hold matrices in packed storage have names ending in p ; arrays with matrices in band storage have names ending in b ; arrays with matrices in RFP storage have names ending in fp .

For more information on matrix storage schemes, see “[Matrix Arguments](#)” in Appendix B.

Mathematical Notation

Descriptions of LAPACK routines use the following notation:

$$Ax = b$$

A system of linear equations with an n -by- n matrix $A = \{a_{ij}\}$, a right-hand side vector $b = \{b_i\}$, and an unknown vector $x = \{x_i\}$.

$$AX = B$$

A set of systems with a common matrix A and multiple right-hand sides. The columns of B are individual right-hand sides, and the columns of x are the corresponding solutions.

$$|x|$$

the vector with elements $|x_i|$ (absolute values of x_i).

$$|A|$$

the matrix with elements $|a_{ij}|$ (absolute values of a_{ij}).

$$\|x\|_\infty = \max_i |x_i|$$

The *infinity-norm* of the vector x .

$$\|A\|_\infty = \max_i \sum_j |a_{ij}|$$

The *infinity-norm* of the matrix A .

$$\|A\|_1 = \max_j \sum_i |a_{ij}|$$

$$\kappa(A) = \|A\| \|A^{-1}\|$$

The *one-norm* of the matrix A . $\|A\|_1 = \|A^T\|_\infty = \|A^H\|_\infty$

The *condition number* of the matrix A .

Error Analysis

In practice, most computations are performed with rounding errors. Besides, you often need to solve a system $Ax = b$, where the data (the elements of A and b) are not known exactly. Therefore, it is important to understand how the data errors and rounding errors can affect the solution x .

Data perturbations. If x is the exact solution of $Ax = b$, and $x + \delta x$ is the exact solution of a perturbed problem $(A + \delta A)x = (b + \delta b)$, then

$$\frac{\|\delta x\|}{\|x\|} \leq \kappa(A) \left(\frac{\|\delta A\|}{\|A\|} + \frac{\|\delta b\|}{\|b\|} \right),$$

where

$$\kappa(A) = \|A\| \|A^{-1}\|.$$

In other words, relative errors in A or b may be amplified in the solution vector x by a factor $\kappa(A) = \|A\| \|A^{-1}\|$ called the *condition number* of A .

Rounding errors have the same effect as relative perturbations $c(n)\varepsilon$ in the original data.

Here ε is the *machine precision*, and $c(n)$ is a modest function of the matrix order n . The corresponding solution error is

$$\|\delta x\| / \|x\| \leq c(n)\kappa(A)\varepsilon. \text{ (The value of } c(n) \text{ is seldom greater than } 10n.)$$

Thus, if your matrix A is *ill-conditioned* (that is, its condition number $\kappa(A)$ is very large), then the error in the solution x is also large; you may even encounter a complete loss of precision.

LAPACK provides routines that allow you to estimate $\kappa(A)$ (see [Routines for Estimating the Condition Number](#)) and also give you a more precise estimate for the actual solution error (see [Refining the Solution and Estimating Its Error](#)).

Computational Routines

Table 3-1 lists the LAPACK computational routines (FORTRAN 77 and Fortran 95 interfaces) for factorizing, equilibrating, and inverting *real* matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error. Table 3-2 lists similar routines for *complex* matrices. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 3-1 Computational Routines for Systems of Equations with Real Matrices

Matrix type, storage scheme	Factorize matrix	Equilibrate matrix	Solve system	Condition number	Estimate error	Invert matrix

In the table above, ? stands for c (single precision complex) or z (double precision complex) for FORTRAN 77 interface.

Routines for Matrix Factorization

This section describes the LAPACK routines for matrix factorization. The following factorizations are supported:

- LU factorization
- Cholesky factorization of real symmetric positive-definite matrices
- Cholesky factorization of real symmetric positive-definite matrices with pivoting
- Cholesky factorization of Hermitian positive-definite matrices
- Cholesky factorization of Hermitian positive-definite matrices with pivoting
- Bunch-Kaufman factorization of real and complex symmetric matrices
- Bunch-Kaufman factorization of Hermitian matrices.

You can compute:

- the LU factorization using full and band storage of matrices
- the Cholesky factorization using full, packed, RFP, and band storage
- the Bunch-Kaufman factorization using full and packed storage.

?getrf

Computes the LU factorization of a general m-by-n matrix.

Syntax

FORTRAN 77:

```
call sgetrf( m, n, a, lda, ipiv, info )
call dgetrf( m, n, a, lda, ipiv, info )
call cgetrf( m, n, a, lda, ipiv, info )
call zgetrf( m, n, a, lda, ipiv, info )
```

Fortran 95:

```
call getrf( a [,ipiv] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes the LU factorization of a general m -by- n matrix A as

$$A = P * L * U,$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$). The routine uses partial pivoting, with row interchanges.

NOTE. This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ; $n \geq 0$.
a	REAL for <code>sgetrf</code> DOUBLE PRECISION for <code>dgetrf</code> COMPLEX for <code>cgetrf</code> DOUBLE COMPLEX for <code>zgetrf</code> . Array, DIMENSION ($lda, *$). Contains the matrix A . The second dimension of a must be at least $\max(1, n)$.
lda	INTEGER. The first dimension of array a .

Output Parameters

a	Overwritten by L and U . The unit diagonal elements of L are not stored.
$ipiv$	INTEGER. Array, DIMENSION at least $\max(1, \min(m, n))$. The pivot indices; for $1 \leq i \leq \min(m, n)$, row i was interchanged with row $ipiv(i)$.
$info$	INTEGER. If $info=0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `getrf` interface are as follows:

<code>a</code>	Holds the matrix A of size (m, n) .
<code>ipiv</code>	Holds the vector of length $\min(m, n)$.

Application Notes

The computed L and U are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(\min(m, n))\epsilon P|L||U|$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision.

The approximate number of floating-point operations for real flavors is

$(2/3)n^3$	If $m = n$,
$(1/3)n^2(3m-n)$	If $m > n$,
$(1/3)m^2(3n-m)$	If $m < n$.

The number of operations for complex flavors is four times greater.

After calling this routine with $m = n$, you can call the following:

<code>?getrs</code>	to solve $A * X = B$ or $A^T X = B$ or $A^H X = B$
<code>?gecon</code>	to estimate the condition number of A
<code>?getri</code>	to compute the inverse of A .

?gbtrf

Computes the LU factorization of a general m -by- n band matrix.

Syntax

FORTRAN 77:

```
call sgbtrf( m, n, kl, ku, ab, ldab, ipiv, info )
call dgbtrf( m, n, kl, ku, ab, ldab, ipiv, info )
call cgbtrf( m, n, kl, ku, ab, ldab, ipiv, info )
call zgbtrf( m, n, kl, ku, ab, ldab, ipiv, info )
```

Fortran 95:

```
call gbtrf( ab [,kl] [,m] [,ipiv] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine forms the LU factorization of a general m -by- n band matrix A with kl non-zero subdiagonals and ku non-zero superdiagonals, that is,

$$A = P*LU,$$

where P is a permutation matrix; L is lower triangular with unit diagonal elements and at most kl non-zero elements in each column; U is an upper triangular band matrix with $kl + ku$ superdiagonals. The routine uses partial pivoting, with row interchanges (which creates the additional kl superdiagonals in U).

NOTE. This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

m INTEGER. The number of rows in matrix A ; $m \geq 0$.

n INTEGER. The number of columns in matrix A ; $n \geq 0$.

<i>kl</i>	INTEGER. The number of subdiagonals within the band of <i>A</i> ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of <i>A</i> ; $ku \geq 0$.
<i>ab</i>	REAL for <i>sgbtrf</i> DOUBLE PRECISION for <i>dgbtrf</i> COMPLEX for <i>cgbtrf</i> DOUBLE COMPLEX for <i>zgbtrf</i> . Array, DIMENSION (<i>ldab</i> , *). The array <i>ab</i> contains the matrix <i>A</i> in band storage, in rows $kl + 1$ to $2*kl + ku + 1$; rows 1 to <i>kl</i> of the array need not be set. The <i>j</i> -th column of <i>A</i> is stored in the <i>j</i> -th column of the array <i>ab</i> as follows: $ab(kl + ku + 1 + i - j, j) = a(i, j)$ for $\max(1, j - ku) \leq i \leq \min(m, j + kl)$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> . ($ldab \geq 2*kl + ku + 1$)

Output Parameters

<i>ab</i>	Overwritten by <i>L</i> and <i>U</i> . <i>U</i> is stored as an upper triangular band matrix with $kl + ku$ superdiagonals in rows 1 to $kl + ku + 1$, and the multipliers used during the factorization are stored in rows $kl + ku + 2$ to $2*kl + ku + 1$. See Application Notes below for further details.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, \min(m, n))$. The pivot indices; for $1 \leq i \leq \min(m, n)$, row <i>i</i> was interchanged with row <i>ipiv</i> (<i>i</i>).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , u_{ii} is 0. The factorization has been completed, but <i>U</i> is exactly singular. Division by 0 will occur if you use the factor <i>U</i> for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gbtrf* interface are as follows:

<i>ab</i>	Holds the array <i>A</i> of size $(2*kl + ku + 1, n)$.
-----------	---

<i>ipiv</i>	Holds the vector of length $\min(m, n)$.
<i>kl</i>	If omitted, assumed $kl = ku$.
<i>ku</i>	Restored as $ku = lda - 2 * kl - 1$.
<i>m</i>	If omitted, assumed $m = n$.

Application Notes

The computed L and U are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(kl + ku + 1) \varepsilon P|L||U|$$

$c(k)$ is a modest linear function of k , and ε is the machine precision.

The total number of floating-point operations for real flavors varies between approximately $2n(ku+1)kl$ and $2n(kl+ku+1)kl$. The number of operations for complex flavors is four times greater. All these estimates assume that kl and ku are much less than $\min(m, n)$.

The band storage scheme is illustrated by the following example, when $m = n = 6$, $kl = 2$, $ku = 1$:

on entry	on exit
$\begin{bmatrix} * & * & * & + & + & + \\ * & * & + & + & + & + \\ * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{bmatrix}$	$\begin{bmatrix} * & * & * & U_{14} & U_{25} & U_{36} \\ * & * & U_{13} & U_{24} & U_{35} & U_{46} \\ * & U_{12} & U_{23} & U_{34} & U_{45} & U_{56} \\ U_{11} & U_{22} & U_{33} & U_{44} & U_{55} & U_{66} \\ M_{21} & M_{32} & M_{43} & M_{54} & M_{65} & * \\ M_{31} & M_{42} & M_{53} & M_{64} & * & * \end{bmatrix}$

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

After calling this routine with $m = n$, you can call the following routines:

gbtrs	to solve $A^*X = B$ or $A^T * X = B$ or $A^H * X = B$
gbcon	to estimate the condition number of A .

?gttrf

Computes the LU factorization of a tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sgttrf( n, dl, d, du, du2, ipiv, info )
call dgttrf( n, dl, d, du, du2, ipiv, info )
call cgttrf( n, dl, d, du, du2, ipiv, info )
call zgttrf( n, dl, d, du, du2, ipiv, info )
```

Fortran 95:

```
call gttrf( dl, d, du, du2 [, ipiv] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes the *LU* factorization of a real or complex tridiagonal matrix *A* in the form $A = P * L * U$,

where *P* is a permutation matrix; *L* is lower bidiagonal with unit diagonal elements; and *U* is an upper triangular matrix with nonzeros in only the main diagonal and first two superdiagonals. The routine uses elimination with partial pivoting and row interchanges.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>dl, d, du</i>	REAL for <code>sgttrf</code> DOUBLE PRECISION for <code>dgttrf</code> COMPLEX for <code>cgttrf</code> DOUBLE COMPLEX for <code>zgttrf</code> . Arrays containing elements of <i>A</i> . The array <i>dl</i> of dimension $(n - 1)$ contains the subdiagonal elements of <i>A</i> . The array <i>d</i> of dimension <i>n</i> contains the diagonal elements of <i>A</i> .

The array du of dimension $(n - 1)$ contains the superdiagonal elements of A .

Output Parameters

$d1$	Overwritten by the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A .
d	Overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A .
du	Overwritten by the $(n-1)$ elements of the first superdiagonal of U .
$du2$	REAL for <code>sgttrf</code> DOUBLE PRECISION for <code>dgttrf</code> COMPLEX for <code>cgttrf</code> DOUBLE COMPLEX for <code>zgttrf</code> . Array, dimension $(n - 2)$. On exit, $du2$ contains $(n-2)$ elements of the second superdiagonal of U .
$ipiv$	INTEGER. Array, dimension (n) . The pivot indices: for $1 \leq i \leq n$, row i was interchanged with row $ipiv(i)$. $ipiv(i)$ is always i or $i+1$; $ipiv(i) = i$ indicates a row interchange was not required.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by zero will occur if you use the factor U for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gttrf` interface are as follows:

$d1$	Holds the vector of length $(n-1)$.
d	Holds the vector of length n .
du	Holds the vector of length $(n-1)$.
$du2$	Holds the vector of length $(n-2)$.
$ipiv$	Holds the vector of length n .

Application Notes

?gbtrs to solve $A * X = B$ or $A^T * X = B$ or $A^H * X = B$
?gbcon to estimate the condition number of A .

?dtttrfb

Computes the factorization of a diagonally dominant tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sdttrfb( n, dl, d, du, info )  
call ddttrfb( n, dl, d, du, info )  
call cdttrfb( n, dl, d, du, info )  
call zdttrfb( n, dl, d, du, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The ?dtttrfb routine computes the factorization of a real or complex diagonally dominant tridiagonal matrix A with the BABE (Burning At Both Ends) algorithm in the form

$$A = L_1 * U * L_2$$

where

- L_1, L_2 are lower bidiagonal with unit diagonal elements corresponding to the Gaussian elimination taken from both ends of the matrix.
- U is an upper triangular matrix with nonzeros in only the main diagonal and first two superdiagonals.

Input Parameters

n INTEGER. The order of the matrix A ; $n \geq 0$.
 dl, d, du REAL for sdttrfb
DOUBLE PRECISION for ddttrfb

COMPLEX for `cdttrfb`
 DOUBLE COMPLEX for `zdttrfb`.
 Arrays containing elements of A .
 The array dl of dimension $(n - 1)$ contains the subdiagonal elements of A .
 The array d of dimension n contains the diagonal elements of A .
 The array du of dimension $(n - 1)$ contains the superdiagonal elements of A .

Output Parameters

dl Overwritten by the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A .

d Overwritten by the n diagonal element reciprocals of the upper triangular matrix U from the factorization of A .

$info$ INTEGER. If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info = i$, u_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by zero will occur if you use the factor U for solving a system of linear equations.

Application Notes

A diagonally dominant tridiagonal system is defined such that $|d_i| > |dl_{i-1}| + |du_i|$ for any i :

$$1 < i < n, \text{ and } |d_1| > |du_1|, |d_n| > |dl_{n-1}|$$

The underlying BABE algorithm is designed for diagonally dominant systems. Such systems are free from the numerical stability issue unlike the canonical systems that use elimination with partial pivoting (see [?gttrf](#)). The diagonally dominant systems are much faster than the canonical systems.

NOTE.

- The current implementation of BABE has a potential accuracy issue on very small or large data close to the underflow or overflow threshold respectively. Scale the matrix before applying the solver in the case of such input data.
- Applying the `?dttrfb` factorization to non-diagonally dominant systems may lead to an accuracy loss, or false singularity detected due to no pivoting.

?potrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spotrf( uplo, n, a, lda, info )
call dpotrf( uplo, n, a, lda, info )
call cpotrf( uplo, n, a, lda, info )
call zpotrf( uplo, n, a, lda, info )
```

Fortran 95:

```
call potrf( a [, uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A :

$$\begin{aligned} A &= U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} && \text{if } uplo = 'U' \\ A &= L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} && \text{if } uplo = 'L' \end{aligned}$$

where L is a lower triangular matrix and U is upper triangular.

NOTE. This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

`uplo` CHARACTER*1. Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of A is stored and how A is factored:

	If $uplo = 'U'$, the array a stores the upper triangular part of the matrix A .
	If $uplo = 'L'$, the array a stores the lower triangular part of the matrix A .
n	INTEGER. The order of matrix A ; $n \geq 0$.
a	REAL for <code>spotrf</code> DOUBLE PRECISION for <code>dpotrf</code> COMPLEX for <code>cpotrf</code> DOUBLE COMPLEX for <code>zpotrf</code> . Array, DIMENSION ($lda, *$). The array a contains either the upper or the lower triangular part of the matrix A (see $uplo$). The second dimension of a must be at least $\max(1, n)$.
lda	INTEGER. The first dimension of a .

Output Parameters

a	The upper or lower triangular part of a is overwritten by the Cholesky factor U or L , as specified by $uplo$.
$info$	INTEGER. If $info=0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `potrf` interface are as follows:

a	Holds the matrix A of size (n, n) .
$uplo$	Must be <code>'U'</code> or <code>'L'</code> . The default value is <code>'U'</code> .

Application Notes

If $uplo = 'U'$, the computed factor U is the exact factor of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\varepsilon |U^H| |U|, |e_{ij}| \leq c(n)\varepsilon \sqrt{a_{ii}a_{jj}}$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for $uplo = 'L'$.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

<code>?potrs</code>	to solve $A * X = B$
<code>?pocon</code>	to estimate the condition number of A
<code>?potri</code>	to compute the inverse of A .

?pstrf

Computes the Cholesky factorization with complete pivoting of a real symmetric (complex Hermitian) positive semidefinite matrix.

Syntax

FORTRAN 77:

```
call spstrf( uplo, n, a, lda, piv, rank, tol, work, info )
call dpstrf( uplo, n, a, lda, piv, rank, tol, work, info )
call cpstrf( uplo, n, a, lda, piv, rank, tol, work, info )
call zpstrf( uplo, n, a, lda, piv, rank, tol, work, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes the Cholesky factorization with complete pivoting of a real symmetric (complex Hermitian) positive semidefinite matrix. The form of the factorization is:

$$P' * A * P = U' * U, \text{ if } uplo = 'U' \text{ for real flavors,}$$

$$conjg(P') * A * P = conjg(U') * U, \text{ if } uplo = 'U' \text{ for complex flavors,}$$

$P' * A * P = L * L'$, if $uplo = 'L'$ for real flavors,
 $conjg(P') * A * P = L * conjg(L')$, if $uplo = 'L'$ for complex flavors,

where P is stored as vector piv , 'U' and 'L' are upper and lower triangular matrices respectively.

This algorithm does not attempt to check that A is positive semidefinite. This version of the algorithm calls level 3 BLAS.

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
 Indicates whether the upper or lower triangular part of A is stored:
 If $uplo = 'U'$, the array a stores the upper triangular part of the matrix A , and the strictly lower triangular part of the matrix is not referenced.
 If $uplo = 'L'$, the array a stores the lower triangular part of the matrix A , and the strictly upper triangular part of the matrix is not referenced.

n INTEGER. The order of matrix A ; $n \geq 0$.

a, work REAL for spstrf
 DOUBLE PRECISION for dpstrf
 COMPLEX for cpstrf
 DOUBLE COMPLEX for zpstrf.
 Array a , DIMENSION ($lda, *$). The array a contains either the upper or the lower triangular part of the matrix A (see $uplo$). The second dimension of a must be at least $\max(1, n)$.
 $work(*)$ is a workspace array. The dimension of $work$ is at least $\max(1, 2*n)$.

tol REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 User defined tolerance. If $tol < 0$, then $n * U * \max(a(k,k))$ will be used.
 The algorithm terminates at the $(k-1)$ -th step, if the pivot $\leq tol$.

lda INTEGER. The first dimension of a ; at least $\max(1, n)$.

Output Parameters

a If $info = 0$, the factor U or L from the Cholesky factorization is as described in *Description*.

piv INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array *piv* is such that the nonzero entries are $p(\text{piv}(k), k) = 1$.

rank INTEGER.
The rank of *a* given by the number of steps the algorithm completed.

info INTEGER. If *info* = 0, the execution is successful.
If *info* = -*k*, the *k*-th argument had an illegal value.
If *info* > 0, the matrix *A* is either rank deficient with a computed rank as returned in *rank*, or is indefinite.

?pftrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix using the Rectangular Full Packed (RFP) format .

Syntax

FORTRAN 77:

```
call spftrf( transr, uplo, n, a, info )
call dpftrf( transr, uplo, n, a, info )
call cpftrf( transr, uplo, n, a, info )
call zpftrf( transr, uplo, n, a, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, a Hermitian positive-definite matrix *A*:

$$\begin{array}{ll}
 A = U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} & \text{if } uplo = 'U' \\
 A = L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} & \text{if } uplo = 'L'
 \end{array}$$

where *L* is a lower triangular matrix and *U* is upper triangular.

The matrix *A* is in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

This is the block version of the algorithm, calling Level 3 BLAS.

Input Parameters

<i>transr</i>	CHARACTER*1. Must be 'N', 'T' (for real data) or 'C' (for complex data). If <i>transr</i> = 'N', the Normal <i>transr</i> of RFP <i>A</i> is stored. If <i>transr</i> = 'T', the Transpose <i>transr</i> of RFP <i>A</i> is stored. If <i>transr</i> = 'C', the Conjugate-Transpose <i>transr</i> of RFP <i>A</i> is stored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of <i>A</i> is stored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix <i>A</i> . If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>a</i>	REAL for spftrf DOUBLE PRECISION for dpftrf COMPLEX for cpftrf DOUBLE COMPLEX for zpftrf. Array, DIMENSION $(n*(n+1)/2)$. The array <i>a</i> contains the matrix <i>A</i> in the RFP format.

Output Parameters

<i>a</i>	The upper or lower triangular part of <i>a</i> is overwritten by the Cholesky factor <i>U</i> or <i>L</i> , as specified by <i>info</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = $-i$, the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the leading minor of order <i>i</i> (and therefore the matrix <i>A</i> itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix <i>A</i> .

?pptrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite matrix using packed storage.

Syntax

FORTRAN 77:

```
call spptrf( uplo, n, ap, info )
call dpptrf( uplo, n, ap, info )
call cpptrf( uplo, n, ap, info )
call zpptrf( uplo, n, ap, info )
```

Fortran 95:

```
call pptrf( ap [, uplo] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite packed matrix A :

$$\begin{aligned}
 A &= U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} && \text{if } uplo = 'U' \\
 A &= L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} && \text{if } uplo = 'L'
 \end{aligned}$$

where L is a lower triangular matrix and U is upper triangular.

NOTE. This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of A is packed in the array *ap*, and how A is factored:

If $uplo = 'U'$, the array ap stores the upper triangular part of the matrix A , and A is factored as $U^H * U$.

If $uplo = 'L'$, the array ap stores the lower triangular part of the matrix A ; A is factored as $L * L^H$.

n INTEGER. The order of matrix A ; $n \geq 0$.

ap REAL for `spptrf`
 DOUBLE PRECISION for `dpptrf`
 COMPLEX for `cpptrf`
 DOUBLE COMPLEX for `zpptrf`.
 Array, DIMENSION at least $\max(1, n(n+1)/2)$. The array ap contains either the upper or the lower triangular part of the matrix A (as specified by $uplo$) in packed storage (see [Matrix Storage Schemes](#)).

Output Parameters

ap The upper or lower triangular part of A in packed storage is overwritten by the Cholesky factor U or L , as specified by $uplo$.

$info$ INTEGER. If $info=0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix A .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pptrf` interface are as follows:

ap Holds the array A of size $(n*(n+1)/2)$.

$uplo$ Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If $uplo = 'U'$, the computed factor U is the exact factor of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\epsilon |U^H| |U|, |e_{ij}| \leq c(n)\epsilon \sqrt{a_{ii}a_{jj}}$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for $uplo = 'L'$.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors and $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

<code>?pptrs</code>	to solve $A*X = B$
<code>?ppcon</code>	to estimate the condition number of A
<code>?pptri</code>	to compute the inverse of A .

?pbtrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite band matrix.

Syntax

FORTRAN 77:

```
call spbtrf( uplo, n, kd, ab, ldab, info )
call dpbtrf( uplo, n, kd, ab, ldab, info )
call cpbtrf( uplo, n, kd, ab, ldab, info )
call zpbtrf( uplo, n, kd, ab, ldab, info )
```

Fortran 95:

```
call pbtrf( ab [, uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine forms the Cholesky factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite band matrix A :

$$A = U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} \quad \text{if } uplo = 'U'$$

$A = L^*L^T$ for real data, $A = L^*L^H$ for complex data if *uplo*='L'

where *L* is a lower triangular matrix and *U* is upper triangular.

NOTE. This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of <i>A</i> is stored in the array <i>ab</i> , and how <i>A</i> is factored: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix <i>A</i> ; $kd \geq 0$.
<i>ab</i>	REAL for <i>spbtrf</i> DOUBLE PRECISION for <i>dpbtrf</i> COMPLEX for <i>cpbtrf</i> DOUBLE COMPLEX for <i>zpbtrf</i> . Array, DIMENSION (, *). The array <i>ab</i> contains either the upper or the lower triangular part of the matrix <i>A</i> (as specified by <i>uplo</i>) in band storage (see Matrix Storage Schemes). The second dimension of <i>ab</i> must be at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> . ($ldab \geq kd + 1$)

Output Parameters

<i>ab</i>	The upper or lower triangular part of <i>A</i> (in band storage) is overwritten by the Cholesky factor <i>U</i> or <i>L</i> , as specified by <i>uplo</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the leading minor of order <i>i</i> (and therefore the matrix <i>A</i> itself) is not positive-definite, and the factorization could not be completed. This may indicate an error in forming the matrix <i>A</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbtrf` interface are as follows:

`ab` Holds the array A of size $(kd+1, n)$.
`uplo` Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If `uplo = 'U'`, the computed factor U is the exact factor of a perturbed matrix $A + E$, where

$$|E| \leq c(kd + 1)\varepsilon |U^H| |U|, |e_{ij}| \leq c(kd + 1)\varepsilon \sqrt{a_{ii}a_{jj}}$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for `uplo = 'L'`.

The total number of floating-point operations for real flavors is approximately $n(kd+1)^2$. The number of operations for complex flavors is 4 times greater. All these estimates assume that kd is much less than n .

After calling this routine, you can call the following routines:

`?pbtrs` to solve $A * X = B$
`?pbcon` to estimate the condition number of A .

?pttrf

Computes the factorization of a symmetric (Hermitian) positive-definite tridiagonal matrix.

Syntax

FORTRAN 77:

```
call spttrf( n, d, e, info )
call dpttrf( n, d, e, info )
```

```
call cpttrf( n, d, e, info )
call zpttrf( n, d, e, info )
```

Fortran 95:

```
call pttrf( d, e [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine forms the factorization of a symmetric positive-definite or, for complex data, Hermitian positive-definite tridiagonal matrix A :

$$A = L^*D^*L',$$

where D is diagonal and L is unit lower bidiagonal. The factorization may also be regarded as having the form $A = U^*D^*U$, where D is unit upper bidiagonal.

Input Parameters

n INTEGER. The order of the matrix A ; $n \geq 0$.

d REAL for `spttrf`, `cpttrf`
 DOUBLE PRECISION for `dpttrf`, `zpttrf`.
 Array, dimension (n). Contains the diagonal elements of A .

e REAL for `spttrf`
 DOUBLE PRECISION for `dpttrf`
 COMPLEX for `cpttrf`
 DOUBLE COMPLEX for `zpttrf`. Array, dimension ($n - 1$). Contains the subdiagonal elements of A .

Output Parameters

d Overwritten by the n diagonal elements of the diagonal matrix D from the L^*D^*L' factorization of A .

e Overwritten by the ($n - 1$) off-diagonal elements of the unit bidiagonal factor L or U from the factorization of A .

info INTEGER. If *info* = 0, the execution is successful.
 If *info* = $-i$, the i -th parameter had an illegal value.

If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite; if $i < n$, the factorization could not be completed, while if $i = n$, the factorization was completed, but $d(n) \leq 0$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pttrf` interface are as follows:

d	Holds the vector of length n .
e	Holds the vector of length $(n-1)$.

?sytrf

Computes the Bunch-Kaufman factorization of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssytrf( uplo, n, a, lda, ipiv, work, lwork, info )
call dsytrf( uplo, n, a, lda, ipiv, work, lwork, info )
call csytrf( uplo, n, a, lda, ipiv, work, lwork, info )
call zsytrf( uplo, n, a, lda, ipiv, work, lwork, info )
```

Fortran 95:

```
call sytrf( a [, uplo] [, ipiv] [, info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the factorization of a real/complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is:

$$\text{if } uplo = 'U', A = P * U * D * U^T * P^T$$

if $uplo = 'L'$, $A = P * L * D * L^T * P^T$,

where A is the input matrix, P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

NOTE. This routine supports the Progress Routine feature. See [Progress Routine](#) section for details.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If $uplo = 'U'$, the array a stores the upper triangular part of the matrix A , and A is factored as $P * U * D * U^T * P^T$. If $uplo = 'L'$, the array a stores the lower triangular part of the matrix A , and A is factored as $P * L * D * L^T * P^T$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>a</i>	REAL for <code>ssytrf</code> DOUBLE PRECISION for <code>dsytrf</code> COMPLEX for <code>csytrf</code> DOUBLE COMPLEX for <code>zsytrf</code> . Array, DIMENSION ($lda, *$). The array a contains either the upper or the lower triangular part of the matrix A (see <i>uplo</i>). The second dimension of a must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of a ; at least $\max(1, n)$.
<i>work</i>	Same type as a . A workspace array, dimension at least $\max(1, lwork)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array ($lwork \geq n$). If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See Application Notes for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	The upper or lower triangular part of <i>a</i> is overwritten by details of the block-diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> (or <i>L</i>).
<i>work(1)</i>	If <i>info</i> =0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of <i>D</i> . If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 block, and the <i>i</i> -th row and column of <i>A</i> was interchanged with the <i>k</i> -th row and column. If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i-1</i> , and (<i>i-1</i>)-th row and column of <i>A</i> was interchanged with the <i>m</i> -th row and column. If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i+1</i> , and (<i>i+1</i>)-th row and column of <i>A</i> was interchanged with the <i>m</i> -th row and column.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , d_{ii} is 0. The factorization has been completed, but <i>D</i> is exactly singular. Division by 0 will occur if you use <i>D</i> for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sytrf* interface are as follows:

<i>a</i>	holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>)
<i>ipiv</i>	holds the vector of length <i>n</i>
<i>uplo</i>	must be 'U' or 'L'. The default value is 'U'.

Application Notes

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The 2-by-2 unit diagonal blocks and the unit diagonal elements of U and L are not stored. The remaining elements of U and L are stored in the corresponding columns of the array a , but additional row interchanges are required to recover U or L explicitly (which is seldom necessary).

If $ipiv(i) = i$ for all $i = 1 \dots n$, then all off-diagonal elements of U (L) are stored explicitly in the corresponding elements of the array a .

If $uplo = 'U'$, the computed factors U and D are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\epsilon P|U||D||U^T|P^T$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision. A similar estimate holds for the computed L and D when $uplo = 'L'$.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

<code>?sytrs</code>	to solve $A * X = B$
<code>?sycon</code>	to estimate the condition number of A
<code>?sytri</code>	to compute the inverse of A .

?hetrf

Computes the Bunch-Kaufman factorization of a complex Hermitian matrix.

Syntax

FORTRAN 77:

```
call chetrf( uplo, n, a, lda, ipiv, work, lwork, info )
call zhetrf( uplo, n, a, lda, ipiv, work, lwork, info )
```

Fortran 95:

```
call hetrf( a [, uplo] [,ipiv] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

if $uplo='U'$, $A = P*U*D*U^H*P^T$

if $uplo='L'$, $A = P*L*D*L^H*P^T$,

where A is the input matrix, P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

NOTE. This routine supports the Progress Routine feature. See [Progress Routine](#) section for details.

Input Parameters

`uplo` CHARACTER*1. Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of A is stored and how A is factored:

	<p>If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix <i>A</i>, and <i>A</i> is factored as $P^*U^*D^*U^H^*P^T$.</p> <p>If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix <i>A</i>, and <i>A</i> is factored as $P^*L^*D^*L^H^*P^T$.</p>
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>a, work</i>	<p>COMPLEX for <code>chetr</code></p> <p>DOUBLE COMPLEX for <code>zhetr</code>.</p> <p>Arrays, DIMENSION <code>a(lda,*)</code>, <code>work(*)</code>.</p> <p>The array <i>a</i> contains the upper or the lower triangular part of the matrix <i>A</i> (see <i>uplo</i>). The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work(*)</i> is a workspace array of dimension at least $\max(1, lwork)$.</p>
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, n)$.
<i>lwork</i>	<p>INTEGER. The size of the <i>work</i> array ($lwork \geq n$).</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code>.</p> <p>See Application Notes for the suggested value of <i>lwork</i>.</p>

Output Parameters

<i>a</i>	The upper or lower triangular part of <i>a</i> is overwritten by details of the block-diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> (or <i>L</i>).
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>ipiv</i>	<p>INTEGER.</p> <p>Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of <i>D</i>. If <i>ipiv</i>(<i>i</i>) = <i>k</i> > 0, then d_{ii} is a 1-by-1 block, and the <i>i</i>-th row and column of <i>A</i> was interchanged with the <i>k</i>-th row and column.</p> <p>If <i>uplo</i> = 'U' and <i>ipiv</i>(<i>i</i>) = <i>ipiv</i>(<i>i</i>-1) = -<i>m</i> < 0, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i</i>-1, and the (<i>i</i>-1)-th row and column of <i>A</i> was interchanged with the <i>m</i>-th row and column.</p> <p>If <i>uplo</i> = 'L' and <i>ipiv</i>(<i>i</i>) = <i>ipiv</i>(<i>i</i>+1) = -<i>m</i> < 0, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i</i>+1, and the (<i>i</i>+1)-th row and column of <i>A</i> was interchanged with the <i>m</i>-th row and column.</p>

info INTEGER. If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.
If *info* = *i*, d_{ii} is 0. The factorization has been completed, but *D* is exactly singular. Division by 0 will occur if you use *D* for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetrf` interface are as follows:

<i>a</i>	holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>)
<i>ipiv</i>	holds the vector of length <i>n</i>
<i>uplo</i>	must be 'U' or 'L'. The default value is 'U'.

Application Notes

This routine is suitable for Hermitian matrices that are not known to be positive-definite. If *A* is in fact positive-definite, the routine does not perform interchanges, and no 2-by-2 diagonal blocks occur in *D*.

For better performance, try using $lwork = n * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The 2-by-2 unit diagonal blocks and the unit diagonal elements of U and L are not stored. The remaining elements of U and L are stored in the corresponding columns of the array a , but additional row interchanges are required to recover U or L explicitly (which is seldom necessary).

If $ipiv(i) = i$ for all $i = 1 \dots n$, then all off-diagonal elements of U (L) are stored explicitly in the corresponding elements of the array a .

If $uplo = 'U'$, the computed factors U and D are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\epsilon P|U||D||U^T|P^T$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision.

A similar estimate holds for the computed L and D when $uplo = 'L'$.

The total number of floating-point operations is approximately $(4/3)n^3$.

After calling this routine, you can call the following routines:

<code>?hetrs</code>	to solve $A^*X = B$
<code>?hecon</code>	to estimate the condition number of A
<code>?hetri</code>	to compute the inverse of A .

?sptf

Computes the Bunch-Kaufman factorization of a symmetric matrix using packed storage.

Syntax

FORTRAN 77:

```
call ssptf( uplo, n, ap, ipiv, info )
call dsptf( uplo, n, ap, ipiv, info )
call csptf( uplo, n, ap, ipiv, info )
call zsptf( uplo, n, ap, ipiv, info )
```

Fortran 95:

```
call sptf( ap [,uplo] [,ipiv] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the factorization of a real/complex symmetric matrix A stored in the packed format using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is:

$$\begin{aligned} \text{if } uplo = 'U', A &= P * U * D * U^T * P^T \\ \text{if } uplo = 'L', A &= P * L * D * L^T * P^T, \end{aligned}$$

where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

NOTE. This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of A is packed in the array <i>ap</i> and how A is factored:</p> <p>If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangular part of the matrix A, and A is factored as $P * U * D * U^T * P^T$.</p> <p>If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangular part of the matrix A, and A is factored as $P * L * D * L^T * P^T$.</p>
<i>n</i>	<p>INTEGER. The order of matrix A; $n \geq 0$.</p>
<i>ap</i>	<p>REAL for <code>ssptf</code></p> <p>DOUBLE PRECISION for <code>dsptf</code></p> <p>COMPLEX for <code>csptf</code></p> <p>DOUBLE COMPLEX for <code>zsptf</code>.</p> <p>Array, DIMENSION at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the upper or the lower triangular part of the matrix A (as specified by <i>uplo</i>) in <i>packed storage</i> (see Matrix Storage Schemes).</p>

Output Parameters

<i>ap</i>	The upper or lower triangle of A (as specified by <i>uplo</i>) is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L).

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spturf` interface are as follows:

<i>ap</i>	Holds the array A of size $(n*(n+1)/2)$.
<i>ipiv</i>	Holds the vector of length n .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The 2-by-2 unit diagonal blocks and the unit diagonal elements of U and L are not stored. The remaining elements of U and L overwrite elements of the corresponding columns of the matrix A , but additional row interchanges are required to recover U or L explicitly (which is seldom necessary).

If $ipiv(i) = i$ for all $i = 1 \dots n$, then all off-diagonal elements of $U(L)$ are stored explicitly in packed form.

If $uplo = 'U'$, the computed factors U and D are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\epsilon P|U||D||U^T|P^T$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision. A similar estimate holds for the computed L and D when $uplo = 'L'$.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors or $(4/3)n^3$ for complex flavors.

After calling this routine, you can call the following routines:

<code>?spttrs</code>	to solve $A * X = B$
<code>?spcon</code>	to estimate the condition number of A
<code>?sptri</code>	to compute the inverse of A .

?hptrf

Computes the Bunch-Kaufman factorization of a complex Hermitian matrix using packed storage.

Syntax

FORTRAN 77:

```
call chptrf( uplo, n, ap, ipiv, info )
```

```
call zhptrf( uplo, n, ap, ipiv, info )
```

Fortran 95:

```
call hptrf( ap [,uplo] [,ipiv] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method:

$$\text{if } uplo = 'U', A = P * U * D * U^H * P^T$$

if $uplo='L'$, $A = P^*L^*D^*L^H*P^T$,

where A is the input matrix, P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .

NOTE. This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of A is packed and how A is factored:
If $uplo = 'U'$, the array *ap* stores the upper triangular part of the matrix A , and A is factored as $P^*U^*D^*U^H*P^T$.
If $uplo = 'L'$, the array *ap* stores the lower triangular part of the matrix A , and A is factored as $P^*L^*D^*L^H*P^T$.

n INTEGER. The order of matrix A ; $n \geq 0$.

ap COMPLEX for `chptrf`
DOUBLE COMPLEX for `zhptrf`.
Array, DIMENSION at least $\max(1, n(n+1)/2)$. The array *ap* contains the upper or the lower triangular part of the matrix A (as specified by *uplo*) in *packed storage* (see [Matrix Storage Schemes](#)).

Output Parameters

ap The upper or lower triangle of A (as specified by *uplo*) is overwritten by details of the block-diagonal matrix D and the multipliers used to obtain the factor U (or L).

ipiv INTEGER.
Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D . If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 block, and the i -th row and column of A was interchanged with the k -th row and column.

If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and the $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and the $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

info INTEGER. If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular. Division by 0 will occur if you use D for solving a system of linear equations.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hptrf` interface are as follows:

<i>ap</i>	Holds the array A of size $(n*(n+1)/2)$.
<i>ipiv</i>	Holds the vector of length n .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The 2-by-2 unit diagonal blocks and the unit diagonal elements of U and L are not stored. The remaining elements of U and L are stored in the corresponding columns of the array a , but additional row interchanges are required to recover U or L explicitly (which is seldom necessary).

If $ipiv(i) = i$ for all $i = 1 \dots n$, then all off-diagonal elements of U (L) are stored explicitly in the corresponding elements of the array a .

If $uplo = 'U'$, the computed factors U and D are the exact factors of a perturbed matrix $A + E$, where

$$|E| \leq c(n)\epsilon P|U||D||U^T|P^T$$

$c(n)$ is a modest linear function of n , and ϵ is the machine precision.

A similar estimate holds for the computed L and D when $uplo = 'L'$.

The total number of floating-point operations is approximately $(4/3)n^3$.

After calling this routine, you can call the following routines:

<code>?hptrs</code>	to solve $A^*X = B$
<code>?hpcon</code>	to estimate the condition number of A
<code>?hptri</code>	to compute the inverse of A .

Routines for Solving Systems of Linear Equations

This section describes the LAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see [Routines for Matrix Factorization](#) in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

?getrs

Solves a system of linear equations with an LU-factored square matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgetrs( trans, n, nrhs, a, lda, ipiv, b, ldb, info )
call dgetrs( trans, n, nrhs, a, lda, ipiv, b, ldb, info )
call cgetrs( trans, n, nrhs, a, lda, ipiv, b, ldb, info )
call zgetrs( trans, n, nrhs, a, lda, ipiv, b, ldb, info )
```

Fortran 95:

```
call getrs( a, ipiv, b [, trans] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the following systems of linear equations:

$$\begin{array}{ll}
 A^*X = B & \text{if } trans = 'N', \\
 A^T * X = B & \text{if } trans = 'T',
 \end{array}$$

$A^{H*X} = B$ if *trans*='C' (for complex matrices only).

Before calling this routine, you must call [?getrf](#) to compute the *LU* factorization of *A*.

Input Parameters

trans CHARACTER*1. Must be 'N' or 'T' or 'C'.
Indicates the form of the equations:
If *trans* = 'N', then $A*X = B$ is solved for *X*.
If *trans* = 'T', then $A^T*X = B$ is solved for *X*.
If *trans* = 'C', then $A^H*X = B$ is solved for *X*.

n INTEGER. The order of *A*; the number of rows in *B* ($n \geq 0$).

nrhs INTEGER. The number of right-hand sides; $nrhs \geq 0$.

a, b REAL for *sgetrs*
DOUBLE PRECISION for *dgetrs*
COMPLEX for *cgetrs*
DOUBLE COMPLEX for *zgetrs*.
Arrays: *a*(*lda*,*), *b*(*ldb*,*).
The array *a* contains *LU* factorization of matrix *A* resulting from the call of [?getrf](#).
The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.
The second dimension of *a* must be at least $\max(1, n)$, the second dimension of *b* at least $\max(1, nrhs)$.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, n)$.

ldb INTEGER. The first dimension of *b*; $ldb \geq \max(1, n)$.

ipiv INTEGER.
Array, DIMENSION at least $\max(1, n)$. The *ipiv* array, as returned by [?getrf](#).

Output Parameters

b Overwritten by the solution matrix *X*.

info INTEGER. If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `getrs` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>ipiv</code>	Holds the vector of length n .
<code>trans</code>	Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|L||U|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \frac{\| |A^{-1}| |A| |x| \|_\infty}{\|x\|_\infty} \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?gecon](#).

To refine the solution and estimate the error, call [?gerfs](#).

?gbtrs

Solves a system of linear equations with an *LU*-factored band matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgbtrs( trans, n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call dgbtrs( trans, n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call cgbtrs( trans, n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call zgbtrs( trans, n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
```

Fortran 95:

```
call gbtrs( ab, b, ipiv, [, kl] [, trans] [, info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the following systems of linear equations:

$A * X = B$	if $trans = 'N'$,
$A^T * X = B$	if $trans = 'T'$,
$A^H * X = B$	if $trans = 'C'$ (for complex matrices only).

Here A is an *LU*-factored general band matrix of order n with kl non-zero subdiagonals and ku nonzero superdiagonals. Before calling this routine, call `?gbtrf` to compute the *LU* factorization of A .

Input Parameters

$trans$	CHARACTER*1. Must be 'N' or 'T' or 'C'.
n	INTEGER. The order of A ; the number of rows in B ; $n \geq 0$.
kl	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
ku	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.

<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab, b</i>	REAL for <i>sgbtrs</i> DOUBLE PRECISION for <i>dgbtrs</i> COMPLEX for <i>cgbtrs</i> DOUBLE COMPLEX for <i>zgbtrs</i> . Arrays: <i>ab</i> (<i>ldab</i> ,*), <i>b</i> (<i>ldb</i> ,*). The array <i>ab</i> contains the matrix <i>A</i> in <i>band storage</i> (see Matrix Storage Schemes). The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>ab</i> must be at least $\max(1, n)$, and the second dimension of <i>b</i> at least $\max(1, nrhs)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ; $ldab \geq 2 * kl + ku + 1$.
<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?gbtrf .

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gbtrs* interface are as follows:

<i>ab</i>	Holds the array <i>A</i> of size $(2 * kl + ku + 1, n)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length $\min(m, n)$.
<i>kl</i>	If omitted, assumed $kl = ku$.
<i>ku</i>	Restored as $lda - 2 * kl - 1$.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(kl + ku + 1)\varepsilon P|L||U|$$

$c(k)$ is a modest linear function of k , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(kl + ku + 1) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector is $2n(ku + 2kl)$ for real flavors. The number of operations for complex flavors is 4 times greater. All these estimates assume that kl and ku are much less than $\min(m, n)$.

To estimate the condition number $\kappa_\infty(A)$, call [?gbcon](#).

To refine the solution and estimate the error, call [?gbrfs](#).

?gttrs

Solves a system of linear equations with a tridiagonal matrix using the LU factorization computed by ?gttrf.

Syntax

FORTRAN 77:

```
call sgttrs( trans, n, nrhs, dl, d, du, du2, ipiv, b, ldb, info )
call dgttrs( trans, n, nrhs, dl, d, du, du2, ipiv, b, ldb, info )
```

```
call cgttrs( trans, n, nrhs, dl, d, du, du2, ipiv, b, ldb, info )
call zgttrs( trans, n, nrhs, dl, d, du, du2, ipiv, b, ldb, info )
```

Fortran 95:

```
call gtttrs( dl, d, du, du2, b, ipiv [, trans] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the following systems of linear equations with multiple right hand sides:

$A^*X = B$ if $trans = 'N'$,
 $A^T * X = B$ if $trans = 'T'$,
 $A^H * X = B$ if $trans = 'C'$ (for complex matrices only).

Before calling this routine, you must call `?gttrf` to compute the LU factorization of A .

Input Parameters

trans CHARACTER*1. Must be 'N' or 'T' or 'C'.
Indicates the form of the equations:
If $trans = 'N'$, then $A^*X = B$ is solved for X .
If $trans = 'T'$, then $A^T * X = B$ is solved for X .
If $trans = 'C'$, then $A^H * X = B$ is solved for X .

n INTEGER. The order of A ; $n \geq 0$.

nrhs INTEGER. The number of right-hand sides, that is, the number of columns in B ; $nrhs \geq 0$.

dl,d,du,du2,b REAL for `sgttrs`
DOUBLE PRECISION for `dgttrs`
COMPLEX for `cgttrs`
DOUBLE COMPLEX for `zgttrs`.
Arrays: $dl(n-1)$, $d(n)$, $du(n-1)$, $du2(n-2)$, $b(ldb, nrhs)$.
The array dl contains the $(n-1)$ multipliers that define the matrix L from the LU factorization of A .
The array d contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A .

The array *du* contains the $(n - 1)$ elements of the first superdiagonal of U .

The array *du2* contains the $(n - 2)$ elements of the second superdiagonal of U .

The array *b* contains the matrix B whose columns are the right-hand sides for the systems of equations.

<i>ldb</i>	INTEGER. The leading dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION (n). The <i>ipiv</i> array, as returned by <code>?gt-trf</code> .

Output Parameters

<i>b</i>	Overwritten by the solution matrix x .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = $-i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gttrs` interface are as follows:

<i>d1</i>	Holds the vector of length $(n-1)$.
<i>d</i>	Holds the vector of length n .
<i>du</i>	Holds the vector of length $(n-1)$.
<i>du2</i>	Holds the vector of length $(n-2)$.
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length n .
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|L||U|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x) \varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $7n$ (including n divisions) for real flavors and $34n$ (including $2n$ divisions) for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call `?gtcon`.

To refine the solution and estimate the error, call `?gtrfs`.

?dttrs

Solves a system of linear equations with a diagonally dominant tridiagonal matrix using the LU factorization computed by ?dttrfb.

Syntax

FORTRAN 77:

```
call sdttrs( trans, n, nrhs, dl, d, du, b, ldb, info )
call ddttrs( trans, n, nrhs, dl, d, du, b, ldb, info )
call cdttrs( trans, n, nrhs, dl, d, du, b, ldb, info )
call zdttrs( trans, n, nrhs, dl, d, du, b, ldb, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The `?dttrs` routine solves the following systems of linear equations with multiple right hand sides for x :

$A * X = B$ if *trans* = 'N',
 $A^T * X = B$ if *trans* = 'T',
 $A^H * X = B$ if *trans* = 'C' (for complex matrices only).

Before calling this routine, call `?dtttrfb` to compute the factorization of *A*.

Input Parameters

trans CHARACTER*1. Must be 'N' or 'T' or 'C'.
 Indicates the form of the equations solved for *x*:
 If *trans* = 'N', then $A * X = B$.
 If *trans* = 'T', then $A^T * X = B$.
 If *trans* = 'C', then $A^H * X = B$.

n INTEGER. The order of *A*; $n \geq 0$.

nrhs INTEGER. The number of right-hand sides, that is, the number of columns in *B*; $nrhs \geq 0$.

dl, d, du, b REAL for `sdttrsb`
 DOUBLE PRECISION for `ddttrsb`
 COMPLEX for `cdttrsb`
 DOUBLE COMPLEX for `zdttrsb`.
 Arrays: $dl(n - 1)$, $d(n)$, $du(n - 1)$, $b(l db, nrhs)$.
 The array *dl* contains the $(n - 1)$ multipliers that define the matrices L_1, L_2 from the factorization of *A*.
 The array *d* contains the *n* diagonal elements of the upper triangular matrix *U* from the factorization of *A*.
 The array *du* contains the $(n - 1)$ elements of the superdiagonal of *U*.
 The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

ldb INTEGER. The leading dimension of *b*; $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the solution matrix *x*.

info INTEGER. If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

?potrs

Solves a system of linear equations with a Cholesky-factored symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spotrs( uplo, n, nrhs, a, lda, b, ldb, info )
call dpotrs( uplo, n, nrhs, a, lda, b, ldb, info )
call cpotrs( uplo, n, nrhs, a, lda, b, ldb, info )
call zpotrs( uplo, n, nrhs, a, lda, b, ldb, info )
```

Fortran 95:

```
call potrs( a, b [,uplo] [, info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the system of linear equations $A * X = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A , given the Cholesky factorization of A :

$A = U^T * U$ for real data, If `uplo = 'U'`

$A = U^H * U$ for complex

data

$A = L * L^T$ for real data, If `uplo = 'L'`,

$A = L * L^H$ for complex

data

where L is a lower triangular matrix and U is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

Before calling this routine, you must call `?potrf` to compute the Cholesky factorization of A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix <i>A</i> has been factored: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides ($nrhs \geq 0$).
<i>a, b</i>	REAL for <i>spotrs</i> DOUBLE PRECISION for <i>dpotrs</i> COMPLEX for <i>cpotrs</i> DOUBLE COMPLEX for <i>zpotrs</i> . Arrays: <i>a(lda,*)</i> , <i>b(ldb,*)</i> . The array <i>a</i> contains the factor <i>U</i> or <i>L</i> (see <i>uplo</i>). The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>a</i> must be at least $\max(1, n)$, the second dimension of <i>b</i> at least $\max(1, nrhs)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>x</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *potrs* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If `uplo = 'U'`, the computed solution for each right-hand side b is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |U^H| |U|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for `uplo = 'L'`. If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$. The approximate number of floating-point operations for one right-hand side vector b is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call `?pocon`.

To refine the solution and estimate the error, call `?porfs`.

?pftrs

Solves a system of linear equations with a Cholesky-factored symmetric (Hermitian) positive-definite matrix using the Rectangular Full Packed (RFP) format.

Syntax

FORTRAN 77:

```
call spftrs( transr, uplo, n, nrhs, a, b, ldb, info )
call dpftrs( transr, uplo, n, nrhs, a, b, ldb, info )
call cpftrs( transr, uplo, n, nrhs, a, b, ldb, info )
```

```
call zpftrs( transr, uplo, n, nrhs, a, b, ldb, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine solves a system of linear equations $A*X = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A using the Cholesky factorization of A :

$$\begin{array}{ll}
 A = U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} & \text{if } uplo = 'U' \\
 A = L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} & \text{if } uplo = 'L'
 \end{array}$$

computed by `?pfturf`. L stands for a lower triangular matrix and U - for an upper triangular matrix.

The matrix A is in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

<i>transr</i>	CHARACTER*1. Must be 'N', 'T' (for real data) or 'C' (for complex data). If <i>transr</i> = 'N', the Normal <i>transr</i> of RFP A is stored. If <i>transr</i> = 'T', the Transpose <i>transr</i> of RFP A is stored. If <i>transr</i> = 'C', the Conjugate-Transpose <i>transr</i> of RFP A is stored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of the RFP matrix A is stored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A . If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns of the matrix B ; $nrhs \geq 0$.
<i>a, b</i>	REAL for <code>spftrs</code> DOUBLE PRECISION for <code>dpftrs</code> COMPLEX for <code>cpftrs</code> DOUBLE COMPLEX for <code>zpftrs</code> .

Arrays: $a(n*(n+1)/2)$, $b(ldb, nrhs)$. The array a contains the matrix A in the RFP format.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

ldb INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

b The solution matrix X .

info INTEGER. If $info=0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

?pptrs

Solves a system of linear equations with a packed Cholesky-factored symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spptrs( uplo, n, nrhs, ap, b, ldb, info )
call dpptrs( uplo, n, nrhs, ap, b, ldb, info )
call cpptrs( uplo, n, nrhs, ap, b, ldb, info )
call zpptrs( uplo, n, nrhs, ap, b, ldb, info )
```

Fortran 95:

```
call pptrs( ap, b [,uplo] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine solves for x the system of linear equations $A*X = B$ with a packed symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A , given the Cholesky factorization of A :

$A = U^T * U$ for real data, If *uplo* = 'U'

$A = U^H * U$ for complex

data

$A = L * L^T$ for real data, If *uplo* = 'L',

$A = L * L^H$ for complex

data

where *L* is a lower triangular matrix and *U* is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix *B*.

Before calling this routine, you must call [?pptrf](#) to compute the Cholesky factorization of *A*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix <i>A</i> has been factored: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides ($nrhs \geq 0$).
<i>ap, b</i>	REAL for <i>spptrs</i> DOUBLE PRECISION for <i>dpptrs</i> COMPLEX for <i>cpptrs</i> DOUBLE COMPLEX for <i>zpptrs</i> . Arrays: <i>ap</i> (*), <i>b</i> (<i>ldb</i> ,*) The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the factor <i>U</i> or <i>L</i> , as specified by <i>uplo</i> , in <i>packed storage</i> (see Matrix Storage Schemes). The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>x</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pptrs` interface are as follows:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If `uplo = 'U'`, the computed solution for each right-hand side b is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |U^H| |U|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

A similar estimate holds for `uplo = 'L'`.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $2n^2$ for real flavors and $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?ppcon](#).

To refine the solution and estimate the error, call [?pprfs](#).

?pbtrs

Solves a system of linear equations with a Cholesky-factored symmetric (Hermitian) positive-definite band matrix.

Syntax

FORTRAN 77:

```
call spbtrs( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call dpbtrs( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call cpbtrs( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call zpbtrs( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
```

Fortran 95:

```
call pbtrs( ab, b [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for real data a system of linear equations $A \cdot X = B$ with a symmetric positive-definite or, for complex data, Hermitian positive-definite *band* matrix A , given the Cholesky factorization of A :

$A = U^T * U$ for real data, If `uplo='U'`

$A = U^H * U$ for complex

data

$A = L * L^T$ for real data, If `uplo='L'`,

$A = L * L^H$ for complex

data

where L is a lower triangular matrix and U is upper triangular. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

Before calling this routine, you must call [?pbtrf](#) to compute the Cholesky factorization of A in the band storage form.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix <i>A</i> has been factored: If <i>uplo</i> = 'U', the upper triangular factor is stored in <i>ab</i> . If <i>uplo</i> = 'L', the lower triangular factor is stored in <i>ab</i> .
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix <i>A</i> ; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab, b</i>	REAL for <i>spbtrs</i> DOUBLE PRECISION for <i>dpbtrs</i> COMPLEX for <i>cpbtrs</i> DOUBLE COMPLEX for <i>zpbtrs</i> . Arrays: <i>ab</i> (<i>ldab</i> ,*), <i>b</i> (<i>ldb</i> ,*). The array <i>ab</i> contains the Cholesky factor, as returned by the factorization routine, in <i>band storage</i> form. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>ab</i> must be at least $\max(1, n)$, and the second dimension of <i>b</i> at least $\max(1, nrhs)$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; $ldab \geq kd + 1$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *pbtrs* interface are as follows:

<i>ab</i>	Holds the array <i>A</i> of size $(kd+1, n)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(kd + 1)\epsilon P|U^H| |U| \quad \text{or} \quad |E| \leq c(kd + 1)\epsilon P|L^H| |L|$$

$c(k)$ is a modest linear function of *k*, and ϵ is the machine precision.

If x_0 is the true solution, the computed solution *x* satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(kd + 1) \text{cond}(A, x)\epsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector is $4n*kd$ for real flavors and $16n*kd$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?pbcon](#).

To refine the solution and estimate the error, call [?pbrfs](#).

?pttrs

Solves a system of linear equations with a symmetric (Hermitian) positive-definite tridiagonal matrix using the factorization computed by [?pttrf](#).

Syntax

FORTRAN 77:

```
call spttrs( n, nrhs, d, e, b, ldb, info )
```

```
call dpttrs( n, nrhs, d, e, b, ldb, info )
call cpttrs( uplo, n, nrhs, d, e, b, ldb, info )
call zpttrs( uplo, n, nrhs, d, e, b, ldb, info )
```

Fortran 95:

```
call pttrs( d, e, b [,info] )
call pttrs( d, e, b [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x a system of linear equations $Ax = B$ with a symmetric (Hermitian) positive-definite tridiagonal matrix A . Before calling this routine, call `?pttrf` to compute the L^*D^*L' for real data and the L^*D^*L' or U^*D^*U factorization of A for complex data.

Input Parameters

<i>uplo</i>	CHARACTER*1. Used for <code>cpttrs/zpttrs</code> only. Must be 'U' or 'L'. Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and how A is factored: If <i>uplo</i> = 'U', the array <i>e</i> stores the superdiagonal of A , and A is factored as U^*D^*U . If <i>uplo</i> = 'L', the array <i>e</i> stores the subdiagonal of A , and A is factored as L^*D^*L' .
<i>n</i>	INTEGER. The order of A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns of the matrix B ; $nrhs \geq 0$.
<i>d</i>	REAL for <code>spttrs, cpttrs</code> DOUBLE PRECISION for <code>dpttrs, zpttrs</code> . Array, dimension (n). Contains the diagonal elements of the diagonal matrix D from the factorization computed by <code>?pttrf</code> .
<i>e, b</i>	REAL for <code>spttrs</code> DOUBLE PRECISION for <code>dpttrs</code> COMPLEX for <code>cpttrs</code> DOUBLE COMPLEX for <code>zpttrs</code> . Arrays: $e(n-1)$, $b(ldb, nrhs)$.

The array e contains the $(n - 1)$ off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by `?pttrf` (see `uplo`).

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

`ldb` INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

`b` Overwritten by the solution matrix x .

`info` INTEGER. If `info=0`, the execution is successful.
If `info = -i`, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pttrs` interface are as follows:

`d` Holds the vector of length n .

`e` Holds the vector of length $(n-1)$.

`b` Holds the matrix B of size $(n, nrhs)$.

`uplo` Used in complex flavors only. Must be 'U' or 'L'. The default value is 'U'.

?sytrs

Solves a system of linear equations with a UDU- or LDL-factored symmetric matrix.

Syntax

FORTRAN 77:

```
call ssytrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
call dsytrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
call csytrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
```

```
call zsytrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
```

Fortran 95:

```
call sytrs( a, b, ipiv [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the system of linear equations $A \cdot X = B$ with a symmetric matrix A , given the Bunch-Kaufman factorization of A :

$$\text{if } uplo='U', \quad A = P \cdot U \cdot D \cdot U^T \cdot P^T$$

$$\text{if } uplo='L', \quad A = P \cdot L \cdot D \cdot L^T \cdot P^T,$$

where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B . You must supply to this routine the factor U (or L) and the array `ipiv` returned by the factorization routine [?sytrf](#).

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <code>uplo = 'U'</code> , the array <code>a</code> stores the upper triangular factor U of the factorization $A = P \cdot U \cdot D \cdot U^T \cdot P^T$. If <code>uplo = 'L'</code> , the array <code>a</code> stores the lower triangular factor L of the factorization $A = P \cdot L \cdot D \cdot L^T \cdot P^T$.
<code>n</code>	INTEGER. The order of matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<code>ipiv</code>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <code>ipiv</code> array, as returned by ?sytrf .
<code>a, b</code>	REAL for <code>ssytrs</code> DOUBLE PRECISION for <code>dsytrs</code> COMPLEX for <code>csytrs</code> DOUBLE COMPLEX for <code>zsytrs</code> . Arrays: <code>a(lda,*)</code> , <code>b(ldb,*)</code> . The array <code>a</code> contains the factor U or L (see <code>uplo</code>).

The array b contains the matrix B whose columns are the right-hand sides for the system of equations.
 The second dimension of a must be at least $\max(1, n)$, and the second dimension of b at least $\max(1, nrhs)$.

lda INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
 ldb INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the solution matrix x .
 $info$ INTEGER. If $info=0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sytrs` interface are as follows:

a Holds the matrix A of size (n, n) .
 b Holds the matrix B of size $(n, nrhs)$.
 $ipiv$ Holds the vector of length n .
 $uplo$ Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^T|P^T \text{ or } |E| \leq c(n)\varepsilon P|L||D||U^T|P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $2n^2$ for real flavors or $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call `?sycon`.

To refine the solution and estimate the error, call `?syrfss`.

?hetrs

Solves a system of linear equations with a UDU- or LDL-factored Hermitian matrix.

Syntax

FORTRAN 77:

```
call chetrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
call zhetrs( uplo, n, nrhs, a, lda, ipiv, b, ldb, info )
```

Fortran 95:

```
call hetrs( a, b, ipiv [, uplo] [, info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the system of linear equations $A*x = B$ with a Hermitian matrix A , given the Bunch-Kaufman factorization of A :

```
if uplo = 'U'      A = P*U*D*UH*PT
if uplo = 'L'      A = P*L*D*LH*PT,
```

where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B . You must supply to this routine the factor U (or L) and the array $ipiv$ returned by the factorization routine [?hetrf](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the array a stores the upper triangular factor U of the factorization $A = P*U*D*U^H*P^T$. If <i>uplo</i> = 'L', the array a stores the lower triangular factor L of the factorization $A = P*L*D*L^H*P^T$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?hetrf .
<i>a, b</i>	COMPLEX for <i>chetrs</i> DOUBLE COMPLEX for <i>zhetsr</i> . Arrays: $a(lda, *)$, $b(ldb, *)$. The array a contains the factor U or L (see <i>uplo</i>). The array b contains the matrix B whose columns are the right-hand sides for the system of equations. The second dimension of a must be at least $\max(1, n)$, the second dimension of b at least $\max(1, nrhs)$.
<i>lda</i>	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix x .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = $-i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetrs` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^H|P^T \text{ or } |E| \leq c(n)\varepsilon P|L||D||L^H|P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $8n^2$.

To estimate the condition number $\kappa_\infty(A)$, call [?hecon](#).

To refine the solution and estimate the error, call [?herfs](#).

?sptrs

Solves a system of linear equations with a UDU- or LDL-factored symmetric matrix using packed storage.

Syntax

FORTRAN 77:

```
call ssptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call dsptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call csptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call zsptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
```

Fortran 95:

```
call sptrs( ap, b, ipiv [, uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the system of linear equations $A*x = B$ with a symmetric matrix A , given the Bunch-Kaufman factorization of A :

if $uplo='U'$, $A = PUDU^T P^T$
 if $uplo='L'$, $A = PLDL^T P^T$,

where P is a permutation matrix, U and L are upper and lower *packed* triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B . You must supply the factor U (or L) and the array $ipiv$ returned by the factorization routine `?sptrf`.

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
 Indicates how the input matrix A has been factored:
 If $uplo = 'U'$, the array ap stores the packed factor U of the factorization $A = P*U*D*U^T*P^T$. If $uplo = 'L'$, the array ap stores the packed factor L of the factorization $A = P*L*D*L^T*P^T$.

<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?sptfrf .
<i>ap, b</i>	REAL for <i>ssptrs</i> DOUBLE PRECISION for <i>dsptrs</i> COMPLEX for <i>csptrs</i> DOUBLE COMPLEX for <i>zsptrs</i> . Arrays: <i>ap</i> (*), <i>b</i> (<i>ldb</i> ,*). The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the factor <i>U</i> or <i>L</i> , as specified by <i>uplo</i> , in <i>packed storage</i> (see Matrix Storage Schemes). The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the system of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>x</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sptrs* interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^T|P^T \text{ or } |E| \leq c(n)\varepsilon P|L||D||L^T|P^T$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $2n^2$ for real flavors or $8n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call `?spcon`.

To refine the solution and estimate the error, call `?sprfs`.

?hptrs

Solves a system of linear equations with a UDU- or LDL-factored Hermitian matrix using packed storage.

Syntax

FORTRAN 77:

```
call chptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call zhptrs( uplo, n, nrhs, ap, ipiv, b, ldb, info )
```

Fortran 95:

```
call hptrs( ap, b, ipiv [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for X the system of linear equations $A \cdot X = B$ with a Hermitian matrix A , given the Bunch-Kaufman factorization of A :

$$\begin{aligned} \text{if } uplo = 'U', \quad & A = P \cdot U \cdot D \cdot U^H \cdot P^T \\ \text{if } uplo = 'L', \quad & A = P \cdot L \cdot D \cdot L^H \cdot P^T, \end{aligned}$$

where P is a permutation matrix, U and L are upper and lower *packed* triangular matrices with unit diagonal, and D is a symmetric block-diagonal matrix. The system is solved with multiple right-hand sides stored in the columns of the matrix B .

You must supply to this routine the arrays ap (containing U or L) and $ipiv$ in the form returned by the factorization routine [?hptrf](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If $uplo = 'U'$, the array ap stores the packed factor U of the factorization $A = P \cdot U \cdot D \cdot U^H \cdot P^T$. If $uplo = 'L'$, the array ap stores the packed factor L of the factorization $A = P \cdot L \cdot D \cdot L^H \cdot P^T$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The $ipiv$ array, as returned by ?hptrf .
<i>ap, b</i>	COMPLEX for <code>chptrs</code> DOUBLE COMPLEX for <code>zhptrs</code> . Arrays: $ap(*), b(l,ldb,*)$. The dimension of ap must be at least $\max(1, n(n+1)/2)$. The array ap contains the factor U or L , as specified by $uplo$, in <i>packed storage</i> (see Matrix Storage Schemes). The array b contains the matrix B whose columns are the right-hand sides for the system of equations. The second dimension of b must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>x</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hptrs` interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon P|U||D||U^H|P^T \text{ or } |E| \leq c(n)\varepsilon P|L||D||L^H|P^T$$

$c(n)$ is a modest linear function of *n*, and ε is the machine precision.

If x_0 is the true solution, the computed solution *x* satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$.

The total number of floating-point operations for one right-hand side vector is approximately $8n^2$ for complex flavors.

To estimate the condition number $\kappa_{\infty}(A)$, call `?hpcon`.

To refine the solution and estimate the error, call `?hprfs`.

?trtrs

Solves a system of linear equations with a triangular matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call strtrs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, info )
call dtrtrs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, info )
call ctrtrs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, info )
call ztrtrs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, info )
```

Fortran 95:

```
call trtrs( a, b [,uplo] [, trans] [,diag] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the following systems of linear equations with a triangular matrix A , with multiple right-hand sides stored in B :

$A * X = B$	if $trans = 'N'$,
$A^T * X = B$	if $trans = 'T'$,
$A^H * X = B$	if $trans = 'C'$ (for complex matrices only).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If $uplo = 'U'$, then A is upper triangular. If $uplo = 'L'$, then A is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'.

	<p>If <i>trans</i> = 'N', then $A^*X = B$ is solved for X. If <i>trans</i> = 'T', then $A^T * X = B$ is solved for X. If <i>trans</i> = 'C', then $A^H * X = B$ is solved for X.</p>
<i>diag</i>	<p>CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', then A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array a.</p>
<i>n</i>	INTEGER. The order of A ; the number of rows in B ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a, b</i>	<p>REAL for <i>strtrs</i> DOUBLE PRECISION for <i>dtrtrs</i> COMPLEX for <i>ctrtrs</i> DOUBLE COMPLEX for <i>ztrtrs</i>. Arrays: $a(lda, *)$, $b(l db, *)$. The array a contains the matrix A. The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of a must be at least $\max(1, n)$, the second dimension of b at least $\max(1, nrhs)$.</p>
<i>lda</i>	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix x .
<i>info</i>	<p>INTEGER. If <i>info</i>=0, the execution is successful. If <i>info</i> = $-i$, the i-th parameter had an illegal value.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trtrs` interface are as follows:

<i>a</i>	Stands for argument <i>ap</i> in FORTRAN 77 interface. Holds the matrix A of size $(n*(n+1)/2)$.
----------	---

<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

For each right-hand side *b*, the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |A|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision. If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_{\infty}}{\|x\|_{\infty}} \leq c(n) \text{cond}(A, x)\varepsilon \text{ provided } c(n) \text{cond}(A, x)\varepsilon < 1$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_{\infty} / \|x\|_{\infty} \leq \| |A^{-1}| \|_{\infty} \| |A| \|_{\infty} = \kappa_{\infty}(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_{\infty}(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_{\infty}(A)$.

The approximate number of floating-point operations for one right-hand side vector b is n^2 for real flavors and $4n^2$ for complex flavors.

To estimate the condition number $\kappa_{\infty}(A)$, call [?trcon](#).

To estimate the error in the solution, call [?trrfs](#).

?tptrs

Solves a system of linear equations with a packed triangular matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call stptrs( uplo, trans, diag, n, nrhs, ap, b, ldb, info )
call dtptrs( uplo, trans, diag, n, nrhs, ap, b, ldb, info )
call ctptrs( uplo, trans, diag, n, nrhs, ap, b, ldb, info )
call ztptrs( uplo, trans, diag, n, nrhs, ap, b, ldb, info )
```

Fortran 95:

```
call tptrs( ap, b [,uplo] [, trans] [,diag] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the following systems of linear equations with a packed triangular matrix A , with multiple right-hand sides stored in B :

$A^*X = B$	if $trans = 'N'$,
$A^T * X = B$	if $trans = 'T'$,
$A^H * X = B$	if $trans = 'C'$ (for complex matrices only).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If $uplo = 'U'$, then A is upper triangular. If $uplo = 'L'$, then A is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. If $trans = 'N'$, then $A^*X = B$ is solved for x . If $trans = 'T'$, then $A^T * X = B$ is solved for x . If $trans = 'C'$, then $A^H * X = B$ is solved for x .
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'.

If *diag* = 'N', then *A* is not a unit triangular matrix.
 If *diag* = 'U', then *A* is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array *ap*.

<i>n</i>	INTEGER. The order of <i>A</i> ; the number of rows in <i>B</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ap, b</i>	REAL for <i>stptrs</i> DOUBLE PRECISION for <i>dtptrs</i> COMPLEX for <i>ctptrs</i> DOUBLE COMPLEX for <i>ztptrs</i> . Arrays: <i>ap</i> (*), <i>b</i> (<i>ldb</i> ,*). The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the matrix <i>A</i> in <i>packed storage</i> (see Matrix Storage Schemes). The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the system of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>x</i> .
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *tpttrs* interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon |A|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon \text{ provided } c(n) \text{cond}(A, x)\varepsilon < 1$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is n^2 for real flavors and $4n^2$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call [?tpcon](#).

To estimate the error in the solution, call [?tprfs](#).

?tbtrs

Solves a system of linear equations with a band triangular matrix, with multiple right-hand sides.

Syntax

FORTRAN 77:

```
call stbtrs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, info )
```

```
call dtbtrs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, info )
```

```
call ctbtrs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, info )
```

```
call ztbtrs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, info )
```

Fortran 95:

```
call tbtrs( ab, b [,uplo] [, trans] [,diag] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the following systems of linear equations with a band triangular matrix A , with multiple right-hand sides stored in B :

$A^*X = B$ if $trans = 'N'$,
 $A^T * X = B$ if $trans = 'T'$,
 $A^H * X = B$ if $trans = 'C'$ (for complex matrices only).

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
 Indicates whether A is upper or lower triangular:
 If $uplo = 'U'$, then A is upper triangular.
 If $uplo = 'L'$, then A is lower triangular.

trans CHARACTER*1. Must be 'N' or 'T' or 'C'.
 If $trans = 'N'$, then $A^*X = B$ is solved for x .
 If $trans = 'T'$, then $A^T * X = B$ is solved for x .
 If $trans = 'C'$, then $A^H * X = B$ is solved for x .

diag CHARACTER*1. Must be 'N' or 'U'.
 If $diag = 'N'$, then A is not a unit triangular matrix.
 If $diag = 'U'$, then A is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array ab .

n INTEGER. The order of A ; the number of rows in B ; $n \geq 0$.

kd INTEGER. The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$.

nrhs INTEGER. The number of right-hand sides; $nrhs \geq 0$.

ab, b REAL for `stbtrs`
 DOUBLE PRECISION for `dtbtrs`
 COMPLEX for `ctbtrs`
 DOUBLE COMPLEX for `ztbtrs`.

Arrays: $ab(ldab, *)$, $b(l\bar{d}b, *)$.

The array ab contains the matrix A in *band storage* form.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

The second dimension of ab must be at least $\max(1, n)$, the second dimension of b at least $\max(1, nrhs)$.

$ldab$ INTEGER. The first dimension of ab ; $ldab \geq kd + 1$.

ldb INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

b Overwritten by the solution matrix x .

$info$ INTEGER. If $info=0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tbtrs` interface are as follows:

ab	Holds the array A of size $(kd+1, n)$
b	Holds the matrix B of size $(n, nrhs)$.
$uplo$	Must be 'U' or 'L'. The default value is 'U'.
$trans$	Must be 'N', 'C', or 'T'. The default value is 'N'.
$diag$	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

For each right-hand side b , the computed solution is the exact solution of a perturbed system of equations $(A + E)x = b$, where

$$|E| \leq c(n)\varepsilon|A|$$

$c(n)$ is a modest linear function of n , and ε is the machine precision. If x_0 is the true solution, the computed solution x satisfies this error bound:

$$\frac{\|x - x_0\|_\infty}{\|x\|_\infty} \leq c(n) \text{cond}(A, x)\varepsilon \text{ provided } c(n) \text{cond}(A, x)\varepsilon < 1$$

where $\text{cond}(A, x) = \| |A^{-1}| |A| |x| \|_\infty / \|x\|_\infty \leq \| |A^{-1}| \|_\infty \| |A| \|_\infty = \kappa_\infty(A)$.

Note that $\text{cond}(A, x)$ can be much smaller than $\kappa_\infty(A)$; the condition number of A^T and A^H might or might not be equal to $\kappa_\infty(A)$.

The approximate number of floating-point operations for one right-hand side vector b is $2n*kd$ for real flavors and $8n*kd$ for complex flavors.

To estimate the condition number $\kappa_\infty(A)$, call `?tbcon`.

To estimate the error in the solution, call `?tbrfs`.

Routines for Estimating the Condition Number

This section describes the LAPACK routines for estimating the *condition number* of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations (see [Error Analysis](#)). Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the *reciprocal* condition number.

?gecon

Estimates the reciprocal of the condition number of a general matrix in the 1-norm or the infinity-norm.

Syntax

FORTRAN 77:

```
call sgecon( norm, n, a, lda, anorm, rcond, work, iwork, info )
call dgecon( norm, n, a, lda, anorm, rcond, work, iwork, info )
call cgecon( norm, n, a, lda, anorm, rcond, work, rwork, info )
call zgecon( norm, n, a, lda, anorm, rcond, work, rwork, info )
```

Fortran 95:

```
call gecon( a, anorm, rcond [,norm] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a general matrix A in the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Before calling this routine:

- compute $anorm$ (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?getrf` to compute the LU factorization of A .

Input Parameters

<i>norm</i>	CHARACTER*1. Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix A in infinity-norm.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a, work</i>	REAL for <code>sgecon</code> DOUBLE PRECISION for <code>dgecon</code> COMPLEX for <code>cgecon</code> DOUBLE COMPLEX for <code>zgecon</code> . Arrays: $a(lda, *)$, $work(*)$. The array a contains the LU -factored matrix A , as returned by <code>?getrf</code> . The second dimension of a must be at least $\max(1, n)$. The array $work$ is a workspace for the routine. The dimension of $work$ must be at least $\max(1, 4*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>anorm</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix A (see Description).

<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>cgecon</i> DOUBLE PRECISION for <i>zgecon</i> . Workspace array, DIMENSION at least $\max(1, 2*n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If $info=0$, the execution is successful. If $info = -i$, the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gecon* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.

Application Notes

The computed *rcond* is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$ or $A^H*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2*n^2$ floating-point operations for real flavors and $8*n^2$ for complex flavors.

?gbcon

Estimates the reciprocal of the condition number of a band matrix in the 1-norm or the infinity-norm.

Syntax

FORTRAN 77:

```
call sgbcon( norm, n, kl, ku, ab, ldab, ipiv, anorm, rcond, work, iwork, info
)
call dgbcon( norm, n, kl, ku, ab, ldab, ipiv, anorm, rcond, work, iwork, info
)
call cgbcon( norm, n, kl, ku, ab, ldab, ipiv, anorm, rcond, work, rwork, info
)
call zgbcon( norm, n, kl, ku, ab, ldab, ipiv, anorm, rcond, work, rwork, info
)
```

Fortran 95:

```
call gbcon( ab, ipiv, anorm, rcond [,kl] [,norm] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a general band matrix A in the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Before calling this routine:

- compute $anorm$ (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?gbtrf](#) to compute the LU factorization of A .

Input Parameters

$norm$ CHARACTER*1. Must be '1' or 'O' or 'I'.

	If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix <i>A</i> in 1-norm.
	If <i>norm</i> = 'I', then the routine estimates the condition number of matrix <i>A</i> in infinity-norm.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of <i>A</i> ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of <i>A</i> ; $ku \geq 0$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> . ($ldab \geq 2*kl + ku + 1$).
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?gbtrf .
<i>ab, work</i>	REAL for sgbcon DOUBLE PRECISION for dgbcon COMPLEX for cgbcon DOUBLE COMPLEX for zgbcon . Arrays: <i>ab</i> (<i>ldab</i> ,*), <i>work</i> (*). The array <i>ab</i> contains the factored band matrix <i>A</i> , as returned by ?gbtrf . The second dimension of <i>ab</i> must be at least $\max(1, n)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>anorm</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix <i>A</i> (see Description).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for cgbcon DOUBLE PRECISION for zgbcon . Workspace array, DIMENSION at least $\max(1, 2*n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors.
--------------	--

An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info INTEGER. If $info=0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbcon` interface are as follows:

<i>ab</i>	Holds the array A of size $(2*k1+ku+1, n)$.
<i>ipiv</i>	Holds the vector of length n .
<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.
<i>k1</i>	If omitted, assumed $k1 = ku$.
<i>ku</i>	Restored as $ku = lda-2*k1-1$.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$ or $A^H*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n(ku + 2k1)$ floating-point operations for real flavors and $8n(ku + 2k1)$ for complex flavors.

?gtcon

Estimates the reciprocal of the condition number of a tridiagonal matrix using the factorization computed by ?gttrf.

Syntax

FORTRAN 77:

```
call sgtcon( norm, n, dl, d, du, du2, ipiv, anorm, rcond, work, iwork, info )
```

```
call dgtcon( norm, n, dl, d, du, du2, ipiv, anorm, rcond, work, iwork, info )
```

```
call cgtcon( norm, n, dl, d, du, du2, ipiv, anorm, rcond, work, info )
```

```
call zgtcon( norm, n, dl, d, du, du2, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call gtcon( dl, d, du, du2, ipiv, anorm, rcond [,norm] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a real or complex tridiagonal matrix A in the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty$$

An estimate is obtained for $\|A^{-1}\|$, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\| \|A^{-1}\|)$.

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call ?gttrf to compute the *LU* factorization of A .

Input Parameters

<i>norm</i>	<p>CHARACTER*1. Must be '1' or 'O' or 'I'.</p> <p>If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix <i>A</i> in 1-norm.</p> <p>If <i>norm</i> = 'I', then the routine estimates the condition number of matrix <i>A</i> in infinity-norm.</p>
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>d1,d,du,du2</i>	<p>REAL for sgtcon DOUBLE PRECISION for dgtcon COMPLEX for cgtcon DOUBLE COMPLEX for zgtcon.</p> <p>Arrays: <i>d1</i>($n - 1$), <i>d</i>(n), <i>du</i>($n - 1$), <i>du2</i>($n - 2$).</p> <p>The array <i>d1</i> contains the ($n - 1$) multipliers that define the matrix <i>L</i> from the <i>LU</i> factorization of <i>A</i> as computed by ?gttrf.</p> <p>The array <i>d</i> contains the <i>n</i> diagonal elements of the upper triangular matrix <i>U</i> from the <i>LU</i> factorization of <i>A</i>.</p> <p>The array <i>du</i> contains the ($n - 1$) elements of the first superdiagonal of <i>U</i>.</p> <p>The array <i>du2</i> contains the ($n - 2$) elements of the second superdiagonal of <i>U</i>.</p>
<i>ipiv</i>	<p>INTEGER.</p> <p>Array, DIMENSION (<i>n</i>). The array of pivot indices, as returned by ?gttrf.</p>
<i>anorm</i>	<p>REAL for single precision flavors. DOUBLE PRECISION for double precision flavors.</p> <p>The norm of the <i>original</i> matrix <i>A</i> (see <i>Description</i>).</p>
<i>work</i>	<p>REAL for sgtcon DOUBLE PRECISION for dgtcon COMPLEX for cgtcon DOUBLE COMPLEX for zgtcon.</p> <p>Workspace array, DIMENSION ($2*n$).</p>
<i>iwork</i>	INTEGER. Workspace array, DIMENSION (<i>n</i>). Used for real flavors only.

Output Parameters

<i>rcond</i>	<p>REAL for single precision flavors. DOUBLE PRECISION for double precision flavors.</p>
--------------	---

An estimate of the reciprocal of the condition number. The routine sets $rcond=0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info INTEGER. If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtcon` interface are as follows:

<i>d1</i>	Holds the vector of length $(n-1)$.
<i>d</i>	Holds the vector of length n .
<i>du</i>	Holds the vector of length $(n-1)$.
<i>du2</i>	Holds the vector of length $(n-2)$.
<i>ipiv</i>	Holds the vector of length n .
<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?pocon

Estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spocon( uplo, n, a, lda, anorm, rcond, work, iwork, info )
call dpocon( uplo, n, a, lda, anorm, rcond, work, iwork, info )
call cpocon( uplo, n, a, lda, anorm, rcond, work, rwork, info )
call zpocon( uplo, n, a, lda, anorm, rcond, work, rwork, info )
```

Fortran 95:

```
call pocon( a, anorm, rcond [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric or Hermitian, } \kappa_\infty(A) = \kappa_1(A)\text{).}$$

Before calling this routine:

- compute $anorm$ (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?potrf` to compute the Cholesky factorization of A .

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <code>uplo</code> = 'U', the upper triangle of A is stored. If <code>uplo</code> = 'L', the lower triangle of A is stored.
<code>n</code>	INTEGER. The order of the matrix A ; $n \geq 0$.
<code>a, work</code>	REAL for <code>spocon</code>

DOUBLE PRECISION for `dpocon`
 COMPLEX for `cpocon`
 DOUBLE COMPLEX for `zpocon`.
 Arrays: `a(lda,*)`, `work(*)`.
 The array `a` contains the factored matrix A , as returned by `?potrf`. The second dimension of `a` must be at least $\max(1, n)$.
 The array `work` is a workspace for the routine. The dimension of `work` must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

`lda` INTEGER. The first dimension of `a`; $lda \geq \max(1, n)$.

`anorm` REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 The norm of the *original* matrix A (see *Description*).

`iwork` INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

`rwork` REAL for `cpocon`
 DOUBLE PRECISION for `zpocon`.
 Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

`rcond` REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 An estimate of the reciprocal of the condition number. The routine sets `rcond` = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime `rcond` is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

`info` INTEGER. If `info` = 0, the execution is successful.
 If `info` = $-i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pocon` interface are as follows:

`a` Holds the matrix A of size (n, n) .

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?ppcon

Estimates the reciprocal of the condition number of a packed symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call sppcon( uplo, n, ap, anorm, rcond, work, iwork, info )
call dppcon( uplo, n, ap, anorm, rcond, work, iwork, info )
call cppcon( uplo, n, ap, anorm, rcond, work, rwork, info )
call zppcon( uplo, n, ap, anorm, rcond, work, rwork, info )
```

Fortran 95:

```
call ppcon( ap, anorm, rcond [,uplo] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a packed symmetric (Hermitian) positive-definite matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric or Hermitian, } \kappa_\infty(A) = \kappa_1(A)\text{)}.$$

Before calling this routine:

- compute $anorm$ (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)

- call `?pptrf` to compute the Cholesky factorization of A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>ap, work</i>	REAL for <code>sppcon</code> DOUBLE PRECISION for <code>dppcon</code> COMPLEX for <code>cppcon</code> DOUBLE COMPLEX for <code>zppcon</code> . Arrays: <i>ap</i> (*), <i>work</i> (*). The array <i>ap</i> contains the packed factored matrix A , as returned by <code>?pptrf</code> . The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>anorm</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix A (see <i>Description</i>).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <code>cppcon</code> DOUBLE PRECISION for <code>zppcon</code> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ppcon` interface are as follows:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?pbcon

Estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite band matrix.

Syntax

FORTRAN 77:

```
call spbcon( uplo, n, kd, ab, ldab, anorm, rcond, work, iwork, info )
call dpbcon( uplo, n, kd, ab, ldab, anorm, rcond, work, iwork, info )
call cpbcon( uplo, n, kd, ab, ldab, anorm, rcond, work, rwork, info )
call zpbcon( uplo, n, kd, ab, ldab, anorm, rcond, work, rwork, info )
```

Fortran 95:

```
call pbcon( ab, anorm, rcond [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite band matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric or Hermitian, } \kappa_\infty(A) = \kappa_1(A)\text{)}.$$

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?pbtrf` to compute the Cholesky factorization of A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the upper triangular factor is stored in <i>ab</i> . If <i>uplo</i> = 'L', the lower triangular factor is stored in <i>ab</i> .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> . ($ldab \geq kd + 1$).
<i>ab, work</i>	REAL for <code>spbcon</code> DOUBLE PRECISION for <code>dpbcon</code> COMPLEX for <code>cpbcon</code> DOUBLE COMPLEX for <code>zpbcon</code> . Arrays: <i>ab</i> (<i>ldab</i> ,*), <i>work</i> (*). The array <i>ab</i> contains the factored matrix A in band form, as returned by <code>?pbtrf</code> . The second dimension of <i>ab</i> must be at least $\max(1, n)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>anorm</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix A (see <i>Description</i>).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <code>cpbcon</code> DOUBLE PRECISION for <code>zpbcon</code> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbcon` interface are as follows:

<i>ab</i>	Holds the array <i>A</i> of size $(kd+1, n)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed *rcond* is never less than x (the reciprocal of the true condition number) and in practice is nearly always less than $10x$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4*n(kd + 1)$ floating-point operations for real flavors and $16*n(kd + 1)$ for complex flavors.

?ptcon

Estimates the reciprocal of the condition number of a symmetric (Hermitian) positive-definite tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sptcon( n, d, e, anorm, rcond, work, info )
```

```
call dptcon( n, d, e, anorm, rcond, work, info )
call cptcon( n, d, e, anorm, rcond, work, info )
call zptcon( n, d, e, anorm, rcond, work, info )
```

Fortran 95:

```
call ptcon( d, e, anorm, rcond [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the reciprocal of the condition number (in the 1-norm) of a real symmetric or complex Hermitian positive-definite tridiagonal matrix using the factorization $A = L^*D^*L^T$ for real flavors and $A = L^*D^*L^H$ for complex flavors or $A = U^T*D*U$ for real flavors and $A = U^H*D*U$ for complex flavors computed by `?pttrf` :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric or Hermitian, } \kappa_\infty(A) = \kappa_1(A)\text{)}.$$

The norm $\|A^{-1}\|_1$ is computed by a direct method, and the reciprocal of the condition number is computed as $rcond = 1 / (\|A\|_1 \|A^{-1}\|_1)$.

Before calling this routine:

- compute *anorm* as $\|A\|_1 = \max_j \sum_i |a_{ij}|$
- call `?pttrf` to compute the factorization of *A*.

Input Parameters

n INTEGER. The order of the matrix *A*; $n \geq 0$.

d, *work* REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Arrays, dimension (*n*).
The array *d* contains the *n* diagonal elements of the diagonal matrix *D* from the factorization of *A*, as computed by `?pttrf` ;
work is a workspace array.

e REAL for `sptcon`
DOUBLE PRECISION for `dptcon`
COMPLEX for `cptcon`
DOUBLE COMPLEX for `zptcon`.

Array, DIMENSION ($n - 1$).
 Contains off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by [?pttrf](#) .

anorm REAL for single precision flavors.
 DOUBLE PRECISION for double precision flavors.
 The 1- norm of the *original* matrix A (see *Description*).

Output Parameters

rcond REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtcon` interface are as follows:

d Holds the vector of length n .
e Holds the vector of length $(n-1)$.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4*n*(kd + 1)$ floating-point operations for real flavors and $16*n*(kd + 1)$ for complex flavors.

?sycon

Estimates the reciprocal of the condition number of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyscon( uplo, n, a, lda, ipiv, anorm, rcond, work, iwork, info )
call dsyscon( uplo, n, a, lda, ipiv, anorm, rcond, work, iwork, info )
call csyscon( uplo, n, a, lda, ipiv, anorm, rcond, work, info )
call zsyscon( uplo, n, a, lda, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call sycon( a, ipiv, anorm, rcond [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a symmetric matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is symmetric, } \kappa_\infty(A) = \kappa_1(A)\text{)}.$$

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?sytrf` to compute the factorization of A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular factor U of the factorization $A = P*U*D*U^T*P^T$. If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular factor L of the factorization $A = P*L*D*L^T*P^T$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.

<i>a, work</i>	<p>REAL for <code>ssycon</code> DOUBLE PRECISION for <code>dsycon</code> COMPLEX for <code>csycon</code> DOUBLE COMPLEX for <code>zsycon</code>. Arrays: <code>a(lda,*)</code>, <code>work(*)</code>. The array <i>a</i> contains the factored matrix <i>A</i>, as returned by <code>?sytrf</code>. The second dimension of <i>a</i> must be at least $\max(1, n)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 2*n)$.</p>
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array <i>ipiv</i> , as returned by <code>?sytrf</code> .
<i>anorm</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix <i>A</i> (see <i>Description</i>).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>rcond</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.</p>
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sycon` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>ipiv</i>	Holds the vector of length <i>n</i> .

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?hecon

Estimates the reciprocal of the condition number of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call checon( uplo, n, a, lda, ipiv, anorm, rcond, work, info )
call zhecon( uplo, n, a, lda, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call hecon( a, ipiv, anorm, rcond [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a Hermitian matrix A :

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 \text{ (since } A \text{ is Hermitian, } \kappa_\infty(A) = \kappa_1(A)\text{)}.$$

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?hetrf](#) to compute the factorization of A .

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.

	Indicates how the input matrix A has been factored: If $uplo = 'U'$, the array a stores the upper triangular factor U of the factorization $A = P*U*D*U^H*P^T$. If $uplo = 'L'$, the array a stores the lower triangular factor L of the factorization $A = P*L*D*L^H*P^T$.
n	INTEGER. The order of matrix A ; $n \geq 0$.
$a, work$	COMPLEX for checon DOUBLE COMPLEX for zhecon. Arrays: $a(lda, *)$, $work(*)$. The array a contains the factored matrix A , as returned by ?hetrf . The second dimension of a must be at least $\max(1, n)$. The array $work$ is a workspace for the routine. The dimension of $work$ must be at least $\max(1, 2*n)$.
lda	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
$ipiv$	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array $ipiv$, as returned by ?hetrf .
$anorm$	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix A (see <i>Description</i>).

Output Parameters

$rcond$	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets $rcond = 0$ if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime $rcond$ is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hecon` interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>ipiv</i>	Holds the vector of length <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

?spcon

Estimates the reciprocal of the condition number of a packed symmetric matrix.

Syntax

FORTRAN 77:

```
call sspcon( uplo, n, ap, ipiv, anorm, rcond, work, iwork, info )
call dspcon( uplo, n, ap, ipiv, anorm, rcond, work, iwork, info )
call cspcon( uplo, n, ap, ipiv, anorm, rcond, work, info )
call zspcon( uplo, n, ap, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call spcon( ap, ipiv, anorm, rcond [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a packed symmetric matrix *A*:

$$\kappa_1(A) = \| |A| \|_1 \| |A^{-1}| \|_1 \text{ (since } A \text{ is symmetric, } \kappa_\infty(A) = \kappa_1(A)\text{)}.$$

Before calling this routine:

- compute *anorm* (either $\| |A| \|_1 = \max_j \sum_i |a_{ij}|$ or $\| |A| \|_\infty = \max_i \sum_j |a_{ij}|$)
- call `?sptrf` to compute the factorization of *A*.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Indicates how the input matrix <i>A</i> has been factored:</p> <p>If <i>uplo</i> = 'U', the array <i>ap</i> stores the packed upper triangular factor <i>U</i> of the factorization $A = P*U*D*U^T*P^T$.</p> <p>If <i>uplo</i> = 'L', the array <i>ap</i> stores the packed lower triangular factor <i>L</i> of the factorization $A = P*L*D*L^T*P^T$.</p>
<i>n</i>	<p>INTEGER. The order of matrix <i>A</i>; $n \geq 0$.</p>
<i>ap, work</i>	<p>REAL for <i>sspcon</i></p> <p>DOUBLE PRECISION for <i>dspcon</i></p> <p>COMPLEX for <i>cspcon</i></p> <p>DOUBLE COMPLEX for <i>zspcon</i>.</p> <p>Arrays: <i>ap</i>(*), <i>work</i>(*).</p> <p>The array <i>ap</i> contains the packed factored matrix <i>A</i>, as returned by ?sptrf. The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$.</p> <p>The array <i>work</i> is a workspace for the routine.</p> <p>The dimension of <i>work</i> must be at least $\max(1, 2*n)$.</p>
<i>ipiv</i>	<p>INTEGER. Array, DIMENSION at least $\max(1, n)$.</p> <p>The array <i>ipiv</i>, as returned by ?sptrf.</p>
<i>anorm</i>	<p>REAL for single precision flavors.</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>The norm of the <i>original</i> matrix <i>A</i> (see <i>Description</i>).</p>
<i>iwork</i>	<p>INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.</p>

Output Parameters

<i>rcond</i>	<p>REAL for single precision flavors.</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.</p>
<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spcon` interface are as follows:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors and $8n^2$ for complex flavors.

?hpcon

Estimates the reciprocal of the condition number of a packed Hermitian matrix.

Syntax

FORTRAN 77:

```
call chpcon( uplo, n, ap, ipiv, anorm, rcond, work, info )
call zhpcon( uplo, n, ap, ipiv, anorm, rcond, work, info )
```

Fortran 95:

```
call hpcon( ap, ipiv, anorm, rcond [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a Hermitian matrix A :

$$\kappa_1(A) = \| |A| \|_1 \| |A^{-1}| \|_1 \text{ (since } A \text{ is Hermitian, } \kappa_\infty(A) = \kappa_1(A)\text{)}.$$

Before calling this routine:

- compute *anorm* (either $\|A\|_1 = \max_j \sum_i |a_{ij}|$ or $\|A\|_\infty = \max_i \sum_j |a_{ij}|$)
- call [?hptrf](#) to compute the factorization of *A*.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix <i>A</i> has been factored: If <i>uplo</i> = 'U', the array <i>ap</i> stores the packed upper triangular factor <i>U</i> of the factorization $A = P*U*D*U^T*P^T$. If <i>uplo</i> = 'L', the array <i>ap</i> stores the packed lower triangular factor <i>L</i> of the factorization $A = P*L*D*L^T*P^T$.
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>ap, work</i>	COMPLEX for <i>chpcon</i> DOUBLE COMPLEX for <i>zhpcon</i> . Arrays: <i>ap</i> (*), <i>work</i> (*). The array <i>ap</i> contains the packed factored matrix <i>A</i> , as returned by ?hptrf . The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 2*n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array <i>ipiv</i> , as returned by ?hptrf .
<i>anorm</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. The norm of the <i>original</i> matrix <i>A</i> (see <i>Description</i>).

Output Parameters

<i>rcond</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbcon` interface are as follows:

`ap` Holds the array A of size $(n*(n+1)/2)$.
`ipiv` Holds the vector of length n .

Application Notes

The computed $rcond$ is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

?trcon

Estimates the reciprocal of the condition number of a triangular matrix.

Syntax

FORTRAN 77:

```
call strcon( norm, uplo, diag, n, a, lda, rcond, work, iwork, info )
call dtrcon( norm, uplo, diag, n, a, lda, rcond, work, iwork, info )
call ctrcon( norm, uplo, diag, n, a, lda, rcond, work, rwork, info )
call ztrcon( norm, uplo, diag, n, a, lda, rcond, work, rwork, info )
```

Fortran 95:

```
call trcon( a, rcond [,uplo] [,diag] [,norm] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a triangular matrix A in either the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Input Parameters

<i>norm</i>	CHARACTER*1. Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix A in infinity-norm.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', the array a stores the upper triangle of A , other array elements are not referenced. If <i>uplo</i> = 'L', the array a stores the lower triangle of A , other array elements are not referenced.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', then A is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array a .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a, work</i>	REAL for <i>strcon</i> DOUBLE PRECISION for <i>dtrcon</i> COMPLEX for <i>ctrcon</i> DOUBLE COMPLEX for <i>ztrcon</i> . Arrays: $a(lda, *)$, $work(*)$. The array a contains the matrix A . The second dimension of a must be at least $\max(1, n)$. The array $work$ is a workspace for the routine. The dimension of $work$ must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>lda</i>	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>ctrcon</i>

DOUBLE PRECISION for `ztrcon`.
 Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

rcond REAL for single precision flavors.
 DOUBLE PRECISION for double precision flavors.
 An estimate of the reciprocal of the condition number. The routine sets *rcond* = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime *rcond* is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.

info INTEGER. If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trcon` interface are as follows:

a Holds the matrix *A* of size (*n*, *n*).

norm Must be '1', 'O', or 'I'. The default value is '1'.

uplo Must be 'U' or 'L'. The default value is 'U'.

diag Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than 10*r*. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors and $4n^2$ operations for complex flavors.

?tpcon

Estimates the reciprocal of the condition number of a packed triangular matrix.

Syntax

FORTRAN 77:

```
call stpcon( norm, uplo, diag, n, ap, rcond, work, iwork, info )
call dtpcon( norm, uplo, diag, n, ap, rcond, work, iwork, info )
call ctpcon( norm, uplo, diag, n, ap, rcond, work, rwork, info )
call ztpcon( norm, uplo, diag, n, ap, rcond, work, rwork, info )
```

Fortran 95:

```
call tpcon( ap, rcond [,uplo] [,diag] [,norm] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a packed triangular matrix A in either the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_\infty(A) = \|A\|_\infty \|A^{-1}\|_\infty = \kappa_1(A^T) = \kappa_1(A^H).$$

Input Parameters

<i>norm</i>	CHARACTER*1. Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix A in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix A in infinity-norm.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangle of A in packed form.

	If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangle of <i>A</i> in packed form.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then <i>A</i> is not a unit triangular matrix. If <i>diag</i> = 'U', then <i>A</i> is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array <i>ap</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>ap, work</i>	REAL for <i>stpcon</i> DOUBLE PRECISION for <i>dtpcon</i> COMPLEX for <i>ctpcon</i> DOUBLE COMPLEX for <i>ztpcon</i> . Arrays: <i>ap</i> (*), <i>work</i> (*). The array <i>ap</i> contains the packed matrix <i>A</i> . The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>ctpcon</i> DOUBLE PRECISION for <i>ztpcon</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tpcon` interface are as follows:

<code>ap</code>	Holds the array <code>A</code> of size $(n*(n+1)/2)$.
<code>norm</code>	Must be '1', 'O', or 'I'. The default value is '1'.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>diag</code>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed `rcond` is never less than r (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors and $4n^2$ operations for complex flavors.

?tbcon

Estimates the reciprocal of the condition number of a triangular band matrix.

Syntax

FORTRAN 77:

```
call stbcon( norm, uplo, diag, n, kd, ab, ldab, rcond, work, iwork, info )
call dtbcon( norm, uplo, diag, n, kd, ab, ldab, rcond, work, iwork, info )
call ctbcon( norm, uplo, diag, n, kd, ab, ldab, rcond, work, rwork, info )
call ztbcon( norm, uplo, diag, n, kd, ab, ldab, rcond, work, rwork, info )
```

Fortran 95:

```
call tbcon( ab, rcond [,uplo] [,diag] [,norm] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates the reciprocal of the condition number of a triangular band matrix `A` in either the 1-norm or infinity-norm:

$$\kappa_1(A) = \|A\|_1 \|A^{-1}\|_1 = \kappa_\infty(A^T) = \kappa_\infty(A^H)$$

$$\kappa_{\infty}(A) = \|A\|_{\infty} \|A^{-1}\|_{\infty} = \kappa_1(A^T) = \kappa_1(A^H).$$

Input Parameters

<i>norm</i>	CHARACTER*1. Must be '1' or 'O' or 'I'. If <i>norm</i> = '1' or 'O', then the routine estimates the condition number of matrix <i>A</i> in 1-norm. If <i>norm</i> = 'I', then the routine estimates the condition number of matrix <i>A</i> in infinity-norm.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether <i>A</i> is upper or lower triangular: If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangle of <i>A</i> in packed form. If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangle of <i>A</i> in packed form.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then <i>A</i> is not a unit triangular matrix. If <i>diag</i> = 'U', then <i>A</i> is unit triangular: diagonal elements are assumed to be 1 and not referenced in the array <i>ab</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix <i>A</i> ; $kd \geq 0$.
<i>ab, work</i>	REAL for stbcon DOUBLE PRECISION for dtbcon COMPLEX for ctbcon DOUBLE COMPLEX for ztbcon. Arrays: <i>ab</i> (<i>ldab</i> ,*), <i>work</i> (*). The array <i>ab</i> contains the band matrix <i>A</i> . The second dimension of <i>ab</i> must be at least $\max(1, n)$. The array <i>work</i> is a workspace for the routine. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> . ($ldab \geq kd + 1$).
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for ctbcon DOUBLE PRECISION for ztbcon. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>rcond</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal of the condition number. The routine sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tbcon` interface are as follows:

<i>ab</i>	Holds the array <i>A</i> of size $(kd+1, n)$.
<i>norm</i>	Must be '1', 'O', or 'I'. The default value is '1'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed *rcond* is never less than *r* (the reciprocal of the true condition number) and in practice is nearly always less than $10r$. A call to this routine involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2*n(kd + 1)$ floating-point operations for real flavors and $8*n(kd + 1)$ operations for complex flavors.

Refining the Solution and Estimating Its Error

This section describes the LAPACK routines for refining the computed solution of a system of linear equations and estimating the solution error. You can call these routines after factorizing the matrix of the system of equations and computing the solution (see [Routines for Matrix Factorization](#) and [Routines for Solving Systems of Linear Equations](#)).

?gerfs

Refines the solution of a system of linear equations with a general matrix and estimates its error.

Syntax

FORTRAN 77:

```
call sgerfs( trans, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, iwork, info )
```

```
call dgerfs( trans, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, iwork, info )
```

```
call cgerfs( trans, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

```
call zgerfs( trans, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call gerfs( a, af, ipiv, b, x [,trans] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ or $A^T * X = B$ or $A^H * X = B$ with a general matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?getrf](#)
- call the solver routine [?getrs](#).

Input Parameters

<i>trans</i>	<p>CHARACTER*1. Must be 'N' or 'T' or 'C'.</p> <p>Indicates the form of the equations:</p> <p>If <i>trans</i> = 'N', the system has the form $A * X = B$.</p> <p>If <i>trans</i> = 'T', the system has the form $A^T * X = B$.</p> <p>If <i>trans</i> = 'C', the system has the form $A^H * X = B$.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i>; $n \geq 0$.</p>
<i>nrhs</i>	<p>INTEGER. The number of right-hand sides; $nrhs \geq 0$.</p>
<i>a,af,b,x,work</i>	<p>REAL for sgerfs DOUBLE PRECISION for dgerfs COMPLEX for cgerfs DOUBLE COMPLEX for zgerfs.</p> <p>Arrays:</p> <p><i>a(lda,*)</i> contains the original matrix <i>A</i>, as supplied to ?getrf.</p> <p><i>af(ldaf,*)</i> contains the factored matrix <i>A</i>, as returned by ?getrf.</p> <p><i>b(ldb,*)</i> contains the right-hand side matrix <i>B</i>.</p> <p><i>x(ldx,*)</i> contains the solution matrix <i>x</i>.</p> <p><i>work(*)</i> is a workspace array.</p> <p>The second dimension of <i>a</i> and <i>af</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.</p>
<i>lda</i>	<p>INTEGER. The first dimension of <i>a</i>; $lda \geq \max(1, n)$.</p>
<i>ldaf</i>	<p>INTEGER. The first dimension of <i>af</i>; $ldaf \geq \max(1, n)$.</p>
<i>ldb</i>	<p>INTEGER. The first dimension of <i>b</i>; $ldb \geq \max(1, n)$.</p>
<i>ldx</i>	<p>INTEGER. The first dimension of <i>x</i>; $ldx \geq \max(1, n)$.</p>
<i>ipiv</i>	<p>INTEGER.</p> <p>Array, DIMENSION at least $\max(1, n)$.</p> <p>The <i>ipiv</i> array, as returned by ?getrf.</p>
<i>iwork</i>	<p>INTEGER.</p> <p>Workspace array, DIMENSION at least $\max(1, n)$.</p>
<i>rwork</i>	<p>REAL for cgerfs DOUBLE PRECISION for zgerfs.</p> <p>Workspace array, DIMENSION at least $\max(1, n)$.</p>

Output Parameters

<i>x</i>	The refined solution matrix <i>x</i> .
<i>ferr</i> , <i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gerfs* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>af</i>	Holds the matrix <i>AF</i> of size (<i>n</i> , <i>n</i>).
<i>ipiv</i>	Holds the vector of length <i>n</i> .
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>nrhs</i>).
<i>x</i>	Holds the matrix <i>x</i> of size (<i>n</i> , <i>nrhs</i>).
<i>ferr</i>	Holds the vector of length (<i>nrhs</i>).
<i>berr</i>	Holds the vector of length (<i>nrhs</i>).
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?gerfsx

Uses extra precise iterative refinement to improve the solution to the system of linear equations with a general matrix A and provides error bounds and backward error estimates.

Syntax

FORTRAN 77:

```
call sgerfsx( trans, equed, n, nrhs, a, lda, af, ldaf, ipiv, r, c, b, ldb, x,  
            ldx, rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params,  
            work, iwork, info )
```

```
call dgerfsx( trans, equed, n, nrhs, a, lda, af, ldaf, ipiv, r, c, b, ldb, x,  
            ldx, rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params,  
            work, iwork, info )
```

```
call cgerfsx( trans, equed, n, nrhs, a, lda, af, ldaf, ipiv, r, c, b, ldb, x,  
            ldx, rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params,  
            work, rwork, info )
```

```
call zgerfsx( trans, equed, n, nrhs, a, lda, af, ldaf, ipiv, r, c, b, ldb, x,  
            ldx, rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params,  
            work, rwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters `equed`, `r`, and `c` below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

`trans` CHARACTER*1. Must be 'N', 'T', or 'C'.

	<p>Specifies the form of the system of equations: If $trans = 'N'$, the system has the form $A * X = B$ (No transpose). If $trans = 'T'$, the system has the form $A^{*T} * X = B$ (Transpose). If $trans = 'C'$, the system has the form $A^{*H} * X = B$ (Conjugate transpose = Transpose).</p>
<i>equed</i>	<p>CHARACTER*1. Must be 'N', 'R', 'C', or 'B'. Specifies the form of equilibration that was done to <i>A</i> before calling this routine. If $equed = 'N'$, no equilibration was done. If $equed = 'R'$, row equilibration was done, that is, <i>A</i> has been premultiplied by $diag(r)$. If $equed = 'C'$, column equilibration was done, that is, <i>A</i> has been postmultiplied by $diag(c)$. If $equed = 'B'$, both row and column equilibration was done, that is, <i>A</i> has been replaced by $diag(r) * A * diag(c)$. The right-hand side <i>B</i> has been changed accordingly.</p>
<i>n</i>	<p>INTEGER. The number of linear equations; the order of the matrix <i>A</i>; $n \geq 0$.</p>
<i>nrhs</i>	<p>INTEGER. The number of right-hand sides; the number of columns of the matrices <i>B</i> and <i>X</i>; $nrhs \geq 0$.</p>
<i>a, af, b, work</i>	<p>REAL for <i>sgerfsx</i> DOUBLE PRECISION for <i>dgerfsx</i> COMPLEX for <i>cgerfsx</i> DOUBLE COMPLEX for <i>zgerfsx</i>. Arrays: $a(lda, *)$, $af(ldaf, *)$, $b(ldb, *)$, $work(*)$. The array <i>a</i> contains the original <i>n</i>-by-<i>n</i> matrix <i>A</i>. The array <i>af</i> contains the factored form of the matrix <i>A</i>, that is, the factors <i>L</i> and <i>U</i> from the factorization $A = P * L * U$ as computed by <code>?getrf</code>. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work(*)</i> is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 4 * n)$ for real flavors, and at least $\max(1, 2 * n)$ for complex flavors.</p>

<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of <i>aF</i> ; $ldaf \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Contains the pivot indices as computed by ?getrf ; for row $1 \leq i \leq n$, row <i>i</i> of the matrix was interchanged with row <i>ipiv</i> (<i>i</i>).
<i>r, c</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: <i>r</i> (<i>n</i>), <i>c</i> (<i>n</i>). The array <i>r</i> contains the row scale factors for <i>A</i> , and the array <i>c</i> contains the column scale factors for <i>A</i> . If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by <i>diag</i> (<i>r</i>); if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed. If <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive. If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by <i>diag</i> (<i>c</i>); if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed. If <i>equed</i> = 'C' or 'B', each element of <i>c</i> must be positive. Each element of <i>r</i> or <i>c</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.
<i>ldb</i>	INTEGER. The first dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$.
<i>x</i>	REAL for sgerfsx DOUBLE PRECISION for dgerfsx COMPLEX for cgerfsx DOUBLE COMPLEX for zgerfsx. Array, DIMENSION (<i>ldx</i> , *). The solution matrix <i>x</i> as computed by ?getrs
<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$.

<i>n_err_bnds</i>	INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in <i>Output Arguments</i> section below.
<i>nparams</i>	INTEGER. Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used.
<i>params</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors.</p> <p>Array, DIMENSION <i>nparams</i>. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <i>nparams</i> = 0, which prevents the source code from accessing the <i>params</i> argument.</p> <p><i>params</i>(<i>la_linrx_itref_i</i> = 1) : Whether to perform iterative refinement or not. Default: 1.0</p> <p>=0.0 No refinement is performed and no error bounds are computed.</p> <p>=1.0 Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION.</p> <p>(Other values are reserved for future use.)</p> <p><i>params</i>(<i>la_linrx_ithresh_i</i> = 2) : Maximum number of residual computations allowed for refinement.</p> <p>Default 10</p> <p>Aggressive Set to 100 to permit convergence using approximate factorizations or factorizations other than <i>LU</i>. If the factorization uses a technique other than Gaussian elimination, the quarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy.</p>

params(*la_linrx_cwise_i* = 3) : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.

Output Parameters

x REAL for sgerfsx
DOUBLE PRECISION for dgerfsx
COMPLEX for cgerfsx
DOUBLE COMPLEX for zgerfsx.
The improved solution matrix *x*.

rcond REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

berr REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of *A* or *B* that makes $x(j)$ an exact solution.

err_bnds_norm REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in *err_bnds_norm*(*i*, :) corresponds to the *i*-th right-hand side.

The second index in *err_bnds_norm*(:, *err*) contains the following three fields:

- err*=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.
- err*=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
- err*=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error

estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z . Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

err_bnds_comp

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:
 Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params*(3) = 0.0), then *err_bnds_comp* is not accessed. If *n_err_bnds* < 3, then at most the first ($:$, *n_err_bnds*) entries are returned.

The first index in *err_bnds_comp*(i , $:$) corresponds to the i -th right-hand side.

The second index in *err_bnds_comp*($:$, *err*) contains the following three fields:

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision flavors.

<i>err=2</i>	<p>"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.</p>
<i>err=3</i>	<p>Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z. Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.</p>
<i>params</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Output parameter only if the input contains erroneous values, namely, in <i>params(1)</i>, <i>params(2)</i>, <i>params(3)</i>. In such a case, the corresponding elements of <i>params</i> are filled with default values on output.</p>
<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful. The solution to every right-hand side is guaranteed. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

If $0 < info \leq n$: $U(info, info)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = n + j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $params(3) = 0.0$, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that $err_bnds_norm(j, 1) = 0.0$ or $err_bnds_comp(j, 1) = 0.0$. See the definition of $err_bnds_norm(; , 1)$ and $err_bnds_comp(; , 1)$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

?gbrfs

Refines the solution of a system of linear equations with a general band matrix and estimates its error.

Syntax

FORTRAN 77:

```
call sgbrfs( trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, b, ldb, x,
            ldx, ferr, berr, work, iwork, info )
```

```
call dgbrfs( trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, b, ldb, x,
            ldx, ferr, berr, work, iwork, info )
```

```
call cgbrfs( trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, b, ldb, x,
            ldx, ferr, berr, work, rwork, info )
```

```
call zgbrfs( trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, b, ldb, x,
            ldx, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call gbrfs( ab, afb, ipiv, b, x [,kl] [,trans] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ or $A^T * X = B$ or $A^H * X = B$ with a band matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine `?gbtrf`
- call the solver routine `?gbtrs`.

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$. If <i>trans</i> = 'T', the system has the form $A^T * X = B$. If <i>trans</i> = 'C', the system has the form $A^H * X = B$.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of sub-diagonals within the band of A ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of super-diagonals within the band of A ; $ku \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab,afb,b,x,work</i>	REAL for <code>sgbrfs</code> DOUBLE PRECISION for <code>dgbrfs</code> COMPLEX for <code>cgbrfs</code> DOUBLE COMPLEX for <code>zgbrfs</code> . Arrays: <i>ab</i> (<i>ldab</i> ,*) contains the original band matrix A , as supplied to <code>?gbtrf</code> , but stored in rows from 1 to $kl + ku + 1$.

$afb(ldafb, *)$ contains the factored band matrix A , as returned by [?gbtrf](#).
 $b(l db, *)$ contains the right-hand side matrix B .
 $x(l dx, *)$ contains the solution matrix X .
 $work(*)$ is a workspace array.
 The second dimension of ab and afb must be at least $\max(1, n)$; the second dimension of b and x must be at least $\max(1, nrhs)$; the dimension of $work$ must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

<i>ldab</i>	INTEGER. The first dimension of <i>ab</i> .
<i>ldafb</i>	INTEGER. The first dimension of <i>afb</i> .
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?gbtrf .
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>cgbrfs</i> DOUBLE PRECISION for <i>zgbrfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix X .
<i>ferr, berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gbrfs* interface are as follows:

<i>ab</i>	Holds the array <i>A</i> of size $(kl+ku+1, n)$.
<i>afb</i>	Holds the array <i>AF</i> of size $(2*kl*ku+1, n)$.
<i>ipiv</i>	Holds the vector of length <i>n</i> .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>kl</i>	If omitted, assumed $kl = ku$.
<i>ku</i>	Restored as $ku = lda-kl-1$.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n(kl + ku)$ floating-point operations (for real flavors) or $16n(kl + ku)$ operations (for complex flavors). In addition, each step of iterative refinement involves $2n(4kl + 3ku)$ operations (for real flavors) or $8n(4kl + 3ku)$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?gbrfsx

Uses extra precise iterative refinement to improve the solution to the system of linear equations with a banded matrix A and provides error bounds and backward error estimates.

Syntax

FORTRAN 77:

```
call sgbrfsx( trans, equed, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, r,
c, b, ldb, x, ldx, rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp,
nparams, params, work, iwork, info )
```

```
call dgbrfsx( trans, equed, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, r,
c, b, ldb, x, ldx, rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp,
nparams, params, work, iwork, info )
```

```
call cgbrfsx( trans, equed, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, r,
c, b, ldb, x, ldx, rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp,
nparams, params, work, rwork, info )
```

```
call zgbrfsx( trans, equed, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, r,
c, b, ldb, x, ldx, rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp,
nparams, params, work, rwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters `equed`, `r`, and `c` below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

<code>trans</code>	CHARACTER*1. Must be 'N', 'T', or 'C'. Specifies the form of the system of equations: If <code>trans</code> = 'N', the system has the form $A \cdot X = B$ (No transpose). If <code>trans</code> = 'T', the system has the form $A^{**T} \cdot X = B$ (Transpose). If <code>trans</code> = 'C', the system has the form $A^{**H} \cdot X = B$ (Conjugate transpose = Transpose).
<code>equed</code>	CHARACTER*1. Must be 'N', 'R', 'C', or 'B'. Specifies the form of equilibration that was done to A before calling this routine. If <code>equed</code> = 'N', no equilibration was done. If <code>equed</code> = 'R', row equilibration was done, that is, A has been premultiplied by <code>diag(r)</code> .

If *equed* = 'C', column equilibration was done, that is, *A* has been postmultiplied by *diag(c)*.
 If *equed* = 'B', both row and column equilibration was done, that is, *A* has been replaced by *diag(r)*A*diag(c)*.
 The right-hand side *B* has been changed accordingly.

n INTEGER. The number of linear equations; the order of the matrix *A*; $n \geq 0$.

kl INTEGER. The number of subdiagonals within the band of *A*; $kl \geq 0$.

ku INTEGER. The number of superdiagonals within the band of *A*; $ku \geq 0$.

nrhs INTEGER. The number of right-hand sides; the number of columns of the matrices *B* and *X*; $nrhs \geq 0$.

ab,afb,b,work REAL for *s*gbrfsx
 DOUBLE PRECISION for *d*gbrfsx
 COMPLEX for *c*gbrfsx
 DOUBLE COMPLEX for *z*gbrfsx.
 Arrays: *ab(ldab,*),afb(ldafb,*),b(lb,*),work(*)*.
 The array *ab* contains the original matrix *A* in band storage, in rows 1 to $kl+ku+1$. The *j*-th column of *A* is stored in the *j*-th column of the array *ab* as follows:
 $ab(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(n,j+kl)$.
 The array *afb* contains details of the LU factorization of the banded matrix *A* as computed by *?gbtrf*. *U* is stored as an upper triangular banded matrix with $kl + ku$ superdiagonals in rows 1 to $kl + ku + 1$. The multipliers used during the factorization are stored in rows $kl + ku + 2$ to $2*kl + ku + 1$.
 The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations. The second dimension of *b* must be at least $\max(1,nrhs)$.
work()* is a workspace array. The dimension of *work* must be at least $\max(1,4*n)$ for real flavors, and at least $\max(1,2*n)$ for complex flavors.

<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; $ldab \geq kl+ku+1..$
<i>ldafb</i>	INTEGER. The first dimension of the array <i>afb</i> ; $ldafb \geq 2*kl+ku+1..$
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Contains the pivot indices as computed by ?gbtrf ; for row $1 \leq i \leq n$, row <i>i</i> of the matrix was interchanged with row <i>ipiv(i)</i> .
<i>r, c</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: <i>r(n), c(n)</i> . The array <i>r</i> contains the row scale factors for <i>A</i> , and the array <i>c</i> contains the column scale factors for <i>A</i> . If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by <i>diag(r)</i> ; if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed. If <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive. If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by <i>diag(c)</i> ; if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed. If <i>equed</i> = 'C' or 'B', each element of <i>c</i> must be positive. Each element of <i>r</i> or <i>c</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.
<i>ldb</i>	INTEGER. The first dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$.
<i>x</i>	REAL for sgbrfsx DOUBLE PRECISION for dgbrfsx COMPLEX for cgbrfsx DOUBLE COMPLEX for zgbrfsx . Array, DIMENSION (<i>ldx, *</i>). The solution matrix <i>x</i> as computed by sgbtrs/dgbtrs for real flavors or cgbtrs/zgbtrs for complex flavors.

<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>n_err_bnds</i>	INTEGER. Number of error bounds to return for each right-hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in <i>Output Arguments</i> section below.
<i>nparams</i>	INTEGER. Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used.
<i>params</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION <i>nparams</i> . Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <i>nparams</i> = 0, which prevents the source code from accessing the <i>params</i> argument. <i>params</i> (<i>la_linrx_itref_i</i> = 1) : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors). =0.0 No refinement is performed and no error bounds are computed. =1.0 Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (Other values are reserved for future use.) <i>params</i> (<i>la_linrx_ithresh_i</i> = 2) : Maximum number of residual computations allowed for refinement. Default 10 Aggressive Set to 100 to permit convergence using approximate factorizations or factorizations other than <i>LU</i> . If the factorization uses a technique other than Gaussian elimination,

the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params(*la_linrx_cwise_i* = 3) : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.

Output Parameters

x REAL for *sgbrfsx*
DOUBLE PRECISION for *dgbrfsx*
COMPLEX for *cgbrfsx*
DOUBLE COMPLEX for *zgbrfsx*.
The improved solution matrix *x*.

rcond REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

berr REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of *A* or *B* that makes $x(j)$ an exact solution.

err_bnds_norm REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in *err_bnds_norm*(*i*, :) corresponds to the *i*-th right-hand side.

The second index in *err_bnds_norm*(:, *err*) contains the following three fields:

- err*=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold *sqrt*(*n*)**slamch*(ϵ) for single precision flavors and *sqrt*(*n*)**diamch*(ϵ) for double precision flavors.
- err*=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold *sqrt*(*n*)**slamch*(ϵ) for single precision flavors and *sqrt*(*n*)**diamch*(ϵ) for double precision flavors. This error bound should only be trusted if the previous boolean is true.
- err*=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold *sqrt*(*n*)**slamch*(ϵ) for single precision flavors and *sqrt*(*n*)**diamch*(ϵ) for double

precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1/(\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z . Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

err_bnds_comp

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:
 Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{\text{true}_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params*(3) = 0.0), then *err_bnds_comp* is not accessed. If *n_err_bnds* < 3, then at most the first ($:$, *n_err_bnds*) entries are returned.

The first index in *err_bnds_comp*(i , $:$) corresponds to the i -th right-hand side.

The second index in *err_bnds_comp*($:$, *err*) contains the following three fields:

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision flavors.

<i>err=2</i>	<p>"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold</p> <p>$\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.</p>
<i>err=3</i>	<p>Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold</p> <p>$\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are</p> <p>$1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z.</p> <p>Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.</p>
<i>params</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Output parameter only if the input contains erroneous values, namely, in <i>params(1)</i>, <i>params(2)</i>, <i>params(3)</i>. In such a case, the corresponding elements of <i>params</i> are filled with default values on output.</p>
<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful. The solution to every right-hand side is guaranteed. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

If $0 < info \leq n$: $U(info, info)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = n + j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $params(3) = 0.0$, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that $err_bnds_norm(j, 1) = 0.0$ or $err_bnds_comp(j, 1) = 0.0$. See the definition of $err_bnds_norm(; , 1)$ and $err_bnds_comp(; , 1)$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

?gtrfs

Refines the solution of a system of linear equations with a tridiagonal matrix and estimates its error.

Syntax

FORTRAN 77:

```
call sgtrfs( trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb, x,
            ldx, ferr, berr, work, iwork, info )
```

```
call dgtrfs( trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb, x,
            ldx, ferr, berr, work, iwork, info )
```

```
call cgtrfs( trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb, x,
            ldx, ferr, berr, work, rwork, info )
```

```
call zgtrfs( trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb, x,
            ldx, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call gtrfs( dl, d, du, dlf, df, duf, du2, ipiv, b, x [,trans] [,ferr] [,berr]
            [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ or $A^T * X = B$ or $A^H * X = B$ with a tridiagonal matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| / |a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| / |b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine `?gttrf`
- call the solver routine `?gttrs`.

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$. If <i>trans</i> = 'T', the system has the form $A^T * X = B$. If <i>trans</i> = 'C', the system has the form $A^H * X = B$.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns of the matrix B ; $nrhs \geq 0$.
<i>dl,d,du,dlf,df,duf,du2,b,x,work</i>	REAL for <code>sgtrfs</code> DOUBLE PRECISION for <code>dgtrfs</code> COMPLEX for <code>cgtrfs</code> DOUBLE COMPLEX for <code>zgtrfs</code> . Arrays: <i>dl</i> , dimension $(n - 1)$, contains the subdiagonal elements of A . <i>d</i> , dimension (n) , contains the diagonal elements of A . <i>du</i> , dimension $(n - 1)$, contains the superdiagonal elements of A .

dL, dimension $(n - 1)$, contains the $(n - 1)$ multipliers that define the matrix *L* from the *LU* factorization of *A* as computed by [?gttrf](#).
dE, dimension (n) , contains the *n* diagonal elements of the upper triangular matrix *U* from the *LU* factorization of *A*.
du1, dimension $(n - 1)$, contains the $(n - 1)$ elements of the first superdiagonal of *U*.
du2, dimension $(n - 2)$, contains the $(n - 2)$ elements of the second superdiagonal of *U*.
b(ldb, nrhs) contains the right-hand side matrix *B*.
x(ldx, nrhs) contains the solution matrix *X*, as computed by [?gttrs](#).
work()* is a workspace array; the dimension of *work* must be at least $\max(1, 3 * n)$ for real flavors and $\max(1, 2 * n)$ for complex flavors.

ldb INTEGER. The first dimension of *b*; $ldb \geq \max(1, n)$.
ldx INTEGER. The first dimension of *x*; $ldx \geq \max(1, n)$.
ipiv INTEGER.
 Array, DIMENSION at least $\max(1, n)$. The *ipiv* array, as returned by [?gttrf](#).
iwork INTEGER. Workspace array, DIMENSION (n) . Used for real flavors only.
rwork REAL for *cgtrfs*
 DOUBLE PRECISION for *zgtrfs*.
 Workspace array, DIMENSION (n) . Used for complex flavors only.

Output Parameters

x The refined solution matrix *X*.
ferr, berr REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
info INTEGER. If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtrfs` interface are as follows:

<code>d1</code>	Holds the vector of length $(n-1)$.
<code>d</code>	Holds the vector of length n .
<code>du</code>	Holds the vector of length $(n-1)$.
<code>d1f</code>	Holds the vector of length $(n-1)$.
<code>df</code>	Holds the vector of length n .
<code>duf</code>	Holds the vector of length $(n-1)$.
<code>du2</code>	Holds the vector of length $(n-2)$.
<code>ipiv</code>	Holds the vector of length n .
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>x</code>	Holds the matrix X of size $(n, nrhs)$.
<code>ferr</code>	Holds the vector of length $(nrhs)$.
<code>berr</code>	Holds the vector of length $(nrhs)$.
<code>trans</code>	Must be 'N', 'C', or 'T'. The default value is 'N'.

?porfs

Refines the solution of a system of linear equations with a symmetric (Hermitian) positive-definite matrix and estimates its error.

Syntax

FORTRAN 77:

```
call sporfs( uplo, n, nrhs, a, lda, af, ldaf, b, ldb, x, ldx, ferr, berr,
work, iwork, info )

call dporfs( uplo, n, nrhs, a, lda, af, ldaf, b, ldb, x, ldx, ferr, berr,
work, iwork, info )

call cporfs( uplo, n, nrhs, a, lda, af, ldaf, b, ldb, x, ldx, ferr, berr,
work, rwork, info )

call zporfs( uplo, n, nrhs, a, lda, af, ldaf, b, ldb, x, ldx, ferr, berr,
work, rwork, info )
```

Fortran 95:

```
call porfs( a, af, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a symmetric (Hermitian) positive definite matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?potrf](#)
- call the solver routine [?potrs](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a,af,b,x,work</i>	REAL for <code>sporfs</code> DOUBLE PRECISION for <code>dporfs</code> COMPLEX for <code>cporfs</code> DOUBLE COMPLEX for <code>zporfs</code> . Arrays: <i>a(lda,*)</i> contains the original matrix A , as supplied to ?potrf . <i>af(ldaf,*)</i> contains the factored matrix A , as returned by ?potrf . <i>b(ldb,*)</i> contains the right-hand side matrix B . <i>x(ldx,*)</i> contains the solution matrix X .

work(*) is a workspace array.

The second dimension of *a* and *af* must be at least $\max(1, n)$; the second dimension of *b* and *x* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of <i>af</i> ; $ldaf \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>cporfs</i> DOUBLE PRECISION for <i>zporfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>x</i> .
<i>ferr, berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *porfs* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>af</i>	Holds the matrix <i>AF</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>x</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.

berr Holds the vector of length (*nrhs*).

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?porfsx

Uses extra precise iterative refinement to improve the solution to the system of linear equations with a symmetric/Hermitian positive-definite matrix A and provides error bounds and backward error estimates.

Syntax

FORTRAN 77:

```
call sporfsx( uplo, equed, n, nrhs, a, lda, af, ldaf, s, b, ldb, x, ldx, rcond,
berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work, iwork,
info )
```

```
call dporfsx( uplo, equed, n, nrhs, a, lda, af, ldaf, s, b, ldb, x, ldx, rcond,
berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work, iwork,
info )
```

```
call cporfsx( uplo, equed, n, nrhs, a, lda, af, ldaf, s, b, ldb, x, ldx, rcond,
berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work, rwork,
info )
```

```
call zporfsx( uplo, equed, n, nrhs, a, lda, af, ldaf, s, b, ldb, x, ldx, rcond,
berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work, rwork,
info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters `equed` and `s` below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <code>uplo</code> = 'U', the upper triangle of A is stored. If <code>uplo</code> = 'L', the lower triangle of A is stored.
<code>equed</code>	CHARACTER*1. Must be 'N' or 'Y'. Specifies the form of equilibration that was done to A before calling this routine. If <code>equed</code> = 'N', no equilibration was done. If <code>equed</code> = 'Y', both row and column equilibration was done, that is, A has been replaced by $diag(s) * A * diag(s)$. The right-hand side B has been changed accordingly.
<code>n</code>	INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.
<code>a, af, b, work</code>	REAL for <code>sporfsx</code> DOUBLE PRECISION for <code>dporfsx</code> COMPLEX for <code>cporfsx</code> DOUBLE COMPLEX for <code>zporfsx</code> . Arrays: <code>a(lda,*)</code> , <code>af(ldaf,*)</code> , <code>b(ldb,*)</code> , <code>work(*)</code> . The array <code>a</code> contains the symmetric/Hermitian matrix A as specified by <code>uplo</code> . If <code>uplo</code> = 'U', the leading n -by- n upper triangular part of <code>a</code> contains the upper triangular part of the

matrix A and the strictly lower triangular part of a is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A and the strictly upper triangular part of a is not referenced. The second dimension of a must be at least $\max(1, n)$.

The array af contains the triangular factor L or U from the Cholesky factorization $A = U^{*}T^{*}U$ or $A = L^{*}L^{*}T^{*}$ as computed by `spotrf` for real flavors or `dpotrf` for complex flavors.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

<i>lda</i>	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of af ; $ldaf \geq \max(1, n)$.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (n). The array s contains the scale factors for A . If $equed = 'N'$, s is not accessed. If $equed = 'Y'$, each element of s must be positive. Each element of s should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.
<i>ldb</i>	INTEGER. The first dimension of the array b ; $ldb \geq \max(1, n)$.
<i>x</i>	REAL for <code>sporfsx</code> DOUBLE PRECISION for <code>dporfsx</code> COMPLEX for <code>cporfsx</code> DOUBLE COMPLEX for <code>zporfsx</code> .

	Array, DIMENSION (<i>ldx</i> , *). The solution matrix <i>x</i> as computed by <code>?potrs</code>
<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>n_err_bnds</i>	INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in <i>Output Arguments</i> section below.
<i>nparams</i>	INTEGER. Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used.
<i>params</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION <i>nparams</i> . Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <i>nparams</i> = 0, which prevents the source code from accessing the <i>params</i> argument. <i>params</i> (<i>la_linrx_itref_i</i> = 1) : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors). =0.0 No refinement is performed and no error bounds are computed. =1.0 Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (Other values are reserved for future use.) <i>params</i> (<i>la_linrx_ithresh_i</i> = 2) : Maximum number of residual computations allowed for refinement. Default 10 Aggressive Set to 100 to permit convergence using approximate factorizations or factorizations other than <i>LU</i> . If the factorization uses a

technique other than Gaussian elimination, the quarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params(*la_linrx_cwise_i* = 3) : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.

Output Parameters

x REAL for *sporfsvx*
DOUBLE PRECISION for *dporfsvx*
COMPLEX for *cporfsvx*
DOUBLE COMPLEX for *zporfsvx*.
The improved solution matrix *x*.

rcond REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

berr REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of *A* or *B* that makes $x(j)$ an exact solution.

err_bnds_norm

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in *err_bnds_norm*(*i*, :) corresponds to the *i*-th right-hand side.

The second index in *err_bnds_norm*(:, *err*) contains the following three fields:

- err*=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.
- err*=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
- err*=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision

flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z . Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

err_bnds_comp

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{\text{true}_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($\text{params}(3) = 0.0$), then *err_bnds_comp* is not accessed. If $n_err_bnds < 3$, then at most the first ($:, n_err_bnds$) entries are returned.

The first index in *err_bnds_comp*($i, :$) corresponds to the i -th right-hand side.

The second index in *err_bnds_comp*($:, err$) contains the following three fields:

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision flavors.

<i>err=2</i>	<p>"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.</p>
<i>err=3</i>	<p>Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z. Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.</p>
<i>params</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Output parameter only if the input contains erroneous values. namely, in <i>params(1)</i>, <i>params(2)</i>, <i>params(3)</i>. In such a case, the corresponding elements of <i>params</i> are filled with default values on output.</p>
<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful. The solution to every right-hand side is guaranteed. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

If $0 < info \leq n$: $U(info, info)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = n + j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $params(3) = 0.0$, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that $err_bnds_norm(j, 1) = 0.0$ or $err_bnds_comp(j, 1) = 0.0$. See the definition of $err_bnds_norm(; , 1)$ and $err_bnds_comp(; , 1)$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

?pprfs

Refines the solution of a system of linear equations with a packed symmetric (Hermitian) positive-definite matrix and estimates its error.

Syntax

FORTRAN 77:

```
call spprfs( uplo, n, nrhs, ap, afp, b, ldb, x, ldx, ferr, berr, work, iwork, info )
```

```
call dpprfs( uplo, n, nrhs, ap, afp, b, ldb, x, ldx, ferr, berr, work, iwork, info )
```

```
call cpprfs( uplo, n, nrhs, ap, afp, b, ldb, x, ldx, ferr, berr, work, rwork, info )
```

```
call zpprfs( uplo, n, nrhs, ap, afp, b, ldb, x, ldx, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call pprfs( ap, afp, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a packed symmetric (Hermitian) positive definite matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine `?pptrf`
- call the solver routine `?pptrs`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <code>uplo</code> = 'U', the upper triangle of A is stored. If <code>uplo</code> = 'L', the lower triangle of A is stored.
<code>n</code>	INTEGER. The order of the matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<code>ap,afp,b,x,work</code>	REAL for <code>spprfs</code> DOUBLE PRECISION for <code>dpprfs</code> COMPLEX for <code>cpprfs</code> DOUBLE COMPLEX for <code>zpprfs</code> . Arrays: <code>ap(*)</code> contains the original packed matrix A , as supplied to <code>?pptrf</code> . <code>afp(*)</code> contains the factored packed matrix A , as returned by <code>?pptrf</code> . <code>b(ldb,*)</code> contains the right-hand side matrix B . <code>x(ldx,*)</code> contains the solution matrix X . <code>work(*)</code> is a workspace array.

The dimension of arrays *ap* and *afp* must be at least $\max(1, n(n+1)/2)$; the second dimension of *b* and *x* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>cpprfs</i> DOUBLE PRECISION for <i>zpprfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr, berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *pprfs* interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>afp</i>	Holds the array <i>AF</i> of size $(n*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?pbrfs

Refines the solution of a system of linear equations with a band symmetric (Hermitian) positive-definite matrix and estimates its error.

Syntax

FORTRAN 77:

```
call spbrfs( uplo, n, kd, nrhs, ab, ldab, afb, ldafb, b, ldb, x, ldx, ferr,
berr, work, iwork, info )
```

```
call dpbrfs( uplo, n, kd, nrhs, ab, ldab, afb, ldafb, b, ldb, x, ldx, ferr,
berr, work, iwork, info )
```

```
call cpbrfs( uplo, n, kd, nrhs, ab, ldab, afb, ldafb, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

```
call zpbrfs( uplo, n, kd, nrhs, ab, ldab, afb, ldafb, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call pbrfs( ab, afb, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine performs an iterative refinement of the solution to a system of linear equations $A * X = B$ with a symmetric (Hermitian) positive definite band matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\| |x - x_e| \|_{\infty} / \|x\|_{\infty}$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?pbtrf](#)
- call the solver routine [?pbtrs](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix A ; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab,afb,b,x,work</i>	REAL for <i>spbrfs</i> DOUBLE PRECISION for <i>dpbrfs</i> COMPLEX for <i>cpbrfs</i> DOUBLE COMPLEX for <i>zpbrfs</i> . Arrays: <i>ab(ldab,*)</i> contains the original band matrix A , as supplied to ?pbtrf . <i>afb(ldafb,*)</i> contains the factored band matrix A , as returned by ?pbtrf . <i>b(l db,*)</i> contains the right-hand side matrix B . <i>x(ldx,*)</i> contains the solution matrix X . <i>work(*)</i> is a workspace array.

The second dimension of ab and afb must be at least $\max(1, n)$; the second dimension of b and x must be at least $\max(1, nrhs)$; the dimension of $work$ must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.

<i>ldab</i>	INTEGER. The first dimension of ab ; $ldab \geq kd + 1$.
<i>ldafb</i>	INTEGER. The first dimension of afb ; $ldafb \geq kd + 1$.
<i>ldb</i>	INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of x ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>cpbrfs</i> DOUBLE PRECISION for <i>zpbrfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

x	The refined solution matrix X .
<i>ferr</i> , <i>berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *pbrfs* interface are as follows:

<i>ab</i>	Holds the array A of size $(kd+1, n)$.
<i>afb</i>	Holds the array AF of size $(kd+1, n)$.
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $8n*kd$ floating-point operations (for real flavors) or $32n*kd$ operations (for complex flavors). In addition, each step of iterative refinement involves $12n*kd$ operations (for real flavors) or $48n*kd$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $4n*kd$ floating-point operations for real flavors or $16n*kd$ for complex flavors.

?ptrfs

Refines the solution of a system of linear equations with a symmetric (Hermitian) positive-definite tridiagonal matrix and estimates its error.

Syntax

FORTRAN 77:

```
call sptrfs( n, nrhs, d, e, df, ef, b, ldb, x, ldx, ferr, berr, work, info )
call dptrfs( n, nrhs, d, e, df, ef, b, ldb, x, ldx, ferr, berr, work, info )
call cptrfs( uplo, n, nrhs, d, e, df, ef, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
call zptrfs( uplo, n, nrhs, d, e, df, ef, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
```

Fortran 95:

```
call ptrfs( d, df, e, ef, b, x [,ferr] [,berr] [,info] )
call ptrfs( d, df, e, ef, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ with a symmetric (Hermitian) positive definite tridiagonal matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine `?pttrf`
- call the solver routine `?pttrs`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Used for complex flavors only. Must be 'U' or 'L'. Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and how A is factored: If <code>uplo = 'U'</code> , the array <code>e</code> stores the superdiagonal of A , and A is factored as $U^H * D * U$. If <code>uplo = 'L'</code> , the array <code>e</code> stores the subdiagonal of A , and A is factored as $L * D * L^H$.
<code>n</code>	INTEGER. The order of the matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<code>d, df, rwork</code>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors Arrays: <code>d(n)</code> , <code>df(n)</code> , <code>rwork(n)</code> . The array <code>d</code> contains the n diagonal elements of the tridiagonal matrix A . The array <code>df</code> contains the n diagonal elements of the diagonal matrix D from the factorization of A as computed by <code>?pttrf</code> . The array <code>rwork</code> is a workspace array used for complex flavors only.
<code>e,ef,b,x,work</code>	REAL for <code>spttrfs</code> DOUBLE PRECISION for <code>dpttrfs</code> COMPLEX for <code>cpttrfs</code> DOUBLE COMPLEX for <code>zpttrfs</code> .

Arrays: $e(n-1)$, $ef(n-1)$, $b(ldb, nrhs)$, $x(ldx, nrhs)$, $work(*)$.
 The array e contains the $(n-1)$ off-diagonal elements of the tridiagonal matrix A (see *uplo*).

The array ef contains the $(n-1)$ off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by `?pttrf` (see *uplo*).

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations.

The array x contains the solution matrix X as computed by `?ptrs`.

The array $work$ is a workspace array. The dimension of $work$ must be at least $2*n$ for real flavors, and at least n for complex flavors.

ldb INTEGER. The leading dimension of b ; $ldb \geq \max(1, n)$.

ldx INTEGER. The leading dimension of x ; $ldx \geq \max(1, n)$.

Output Parameters

x The refined solution matrix X .

ferr, berr REAL for single precision flavors.

DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

info INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ptrfs` interface are as follows:

d Holds the vector of length n .

df Holds the vector of length n .

e Holds the vector of length $(n-1)$.

ef Holds the vector of length $(n-1)$.

b Holds the matrix B of size $(n, nrhs)$.

<code>x</code>	Holds the matrix x of size $(n, nrhs)$.
<code>ferr</code>	Holds the vector of length $(nrhs)$.
<code>berr</code>	Holds the vector of length $(nrhs)$.
<code>uplo</code>	Used in complex flavors only. Must be 'U' or 'L'. The default value is 'U'.

?syrfs

Refines the solution of a system of linear equations with a symmetric matrix and estimates its error.

Syntax

FORTRAN 77:

```
call ssyrfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, iwork, info )
```

```
call dsyrfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, iwork, info )
```

```
call csyrfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

```
call zsyrfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call syrfs( a, af, ipiv, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a symmetric full-storage matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\| |x - x_e| |_{\infty} / \|x| |_{\infty}$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?sytrf](#)
- call the solver routine [?sytrs](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a,af,b,x,work</i>	REAL for <i>ssyrfs</i> DOUBLE PRECISION for <i>dsyrfs</i> COMPLEX for <i>csyrfs</i> DOUBLE COMPLEX for <i>zsyrfs</i> . Arrays: <i>a(lda,*)</i> contains the original matrix <i>A</i> , as supplied to ?sytrf . <i>af(ldaf,*)</i> contains the factored matrix <i>A</i> , as returned by ?sytrf . <i>b(l db,*)</i> contains the right-hand side matrix <i>B</i> . <i>x(ldx,*)</i> contains the solution matrix <i>x</i> . <i>work(*)</i> is a workspace array. The second dimension of <i>a</i> and <i>af</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of <i>af</i> ; $ldaf \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?sytrf .

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
rwork REAL for *csyrfs*
 DOUBLE PRECISION for *zsyrfs*.
 Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

x The refined solution matrix *x*.
ferr, berr REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
info INTEGER. If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *syrfs* interface are as follows:

a Holds the matrix *A* of size (n, n) .
af Holds the matrix *AF* of size (n, n) .
ipiv Holds the vector of length *n*.
b Holds the matrix *B* of size $(n, nrhs)$.
x Holds the matrix *X* of size $(n, nrhs)$.
ferr Holds the vector of length $(nrhs)$.
berr Holds the vector of length $(nrhs)$.
uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations

(for complex flavors); the number of iterations may range from 1 to 5. Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?syrfSX

Uses extra precise iterative refinement to improve the solution to the system of linear equations with a symmetric indefinite matrix A and provides error bounds and backward error estimates.

Syntax

FORTRAN 77:

```
call ssyrfSX( uplo, equed, n, nrhs, a, lda, af, ldaf, ipiv, s, b, ldb, x, ldx,
             rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work,
             iwork, info )
```

```
call dsyrfSX( uplo, equed, n, nrhs, a, lda, af, ldaf, ipiv, s, b, ldb, x, ldx,
             rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work,
             iwork, info )
```

```
call csyrfSX( uplo, equed, n, nrhs, a, lda, af, ldaf, ipiv, s, b, ldb, x, ldx,
             rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work,
             rwork, info )
```

```
call zsyrfSX( uplo, equed, n, nrhs, a, lda, af, ldaf, ipiv, s, b, ldb, x, ldx,
             rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work,
             rwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters *equed* and *s* below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of <i>A</i> is stored: If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.</p>
<i>equed</i>	<p>CHARACTER*1. Must be 'N' or 'Y'. Specifies the form of equilibration that was done to <i>A</i> before calling this routine. If <i>equed</i> = 'N', no equilibration was done. If <i>equed</i> = 'Y', both row and column equilibration was done, that is, <i>A</i> has been replaced by $diag(s)*A*diag(s)$. The right-hand side <i>B</i> has been changed accordingly.</p>
<i>n</i>	<p>INTEGER. The number of linear equations; the order of the matrix <i>A</i>; $n \geq 0$.</p>
<i>nrhs</i>	<p>INTEGER. The number of right-hand sides; the number of columns of the matrices <i>B</i> and <i>X</i>; $nrhs \geq 0$.</p>
<i>a</i> , <i>af</i> , <i>b</i> , <i>work</i>	<p>REAL for <i>ssyrfsx</i> DOUBLE PRECISION for <i>dsyrfsx</i> COMPLEX for <i>csyrfsx</i> DOUBLE COMPLEX for <i>zsyrfsx</i>. Arrays: <i>a(lda,*)</i>, <i>af(ldaf,*)</i>, <i>b(ldb,*)</i>, <i>work(*)</i>. The array <i>a</i> contains the symmetric/Hermitian matrix <i>A</i> as specified by <i>uplo</i>. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i> and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i> and the strictly upper triangular part of <i>a</i> is not referenced. The second dimension of <i>a</i> must be at least $\max(1, n)$.</p>

The array *a**f* contains the triangular factor *L* or *U* from the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T^*$ as computed by `ssytrf` for real flavors or `dsytrf` for complex flavors.

The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations. The second dimension of *b* must be at least $\max(1, nrhs)$.

work(*) is a workspace array. The dimension of *work* must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of <i>a</i> <i>f</i> ; $ldaf \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of <i>D</i> as determined by <code>ssytrf</code> for real flavors or <code>dsytrf</code> for complex flavors.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i> . If <i>equed</i> = 'N', <i>s</i> is not accessed. If <i>equed</i> = 'Y', each element of <i>s</i> must be positive. Each element of <i>s</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.
<i>ldb</i>	INTEGER. The first dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$.
<i>x</i>	REAL for <code>ssyrfsx</code> DOUBLE PRECISION for <code>dsyrfsx</code> COMPLEX for <code>csyrfsx</code> DOUBLE COMPLEX for <code>zsyrfsx</code> . Array, DIMENSION (<i>ldx</i> , *).

	The solution matrix x as computed by <code>?sytrs</code>
<code>ldx</code>	INTEGER. The first dimension of the output array x ; $ldx \geq \max(1, n)$.
<code>n_err_bnds</code>	INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <code>err_bnds_norm</code> and <code>err_bnds_comp</code> descriptions in <i>Output Arguments</i> section below.
<code>nparams</code>	INTEGER. Specifies the number of parameters set in <code>params</code> . If ≤ 0 , the <code>params</code> array is never referenced and default values are used.
<code>params</code>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION <code>nparams</code> . Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to <code>nparams</code> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <code>nparams = 0</code> , which prevents the source code from accessing the <code>params</code> argument. <code>params(la_linrx_itref_i = 1)</code> : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors). =0.0 No refinement is performed and no error bounds are computed. =1.0 Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION. (Other values are reserved for future use.) <code>params(la_linrx_ithresh_i = 2)</code> : Maximum number of residual computations allowed for refinement. Default 10 Aggressive Set to 100 to permit convergence using approximate factorizations or factorizations other than <i>LU</i> . If the factorization uses a technique other than Gaussian elimination,

the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params(*la_linrx_cwise_i* = 3) : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.

Output Parameters

x REAL for *ssyrfsx*
DOUBLE PRECISION for *dsyrfsx*
COMPLEX for *csyrfsx*
DOUBLE COMPLEX for *zsyrfsx*.
The improved solution matrix *x*.

rcond REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

berr REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of *A* or *B* that makes $x(j)$ an exact solution.

err_bnds_norm REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in *err_bnds_norm*(*i*, :) corresponds to the *i*-th right-hand side.

The second index in *err_bnds_norm*(:, *err*) contains the following three fields:

- err*=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold *sqrt*(*n*)**slamch*(ϵ) for single precision flavors and *sqrt*(*n*)**diamch*(ϵ) for double precision flavors.
- err*=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold *sqrt*(*n*)**slamch*(ϵ) for single precision flavors and *sqrt*(*n*)**diamch*(ϵ) for double precision flavors. This error bound should only be trusted if the previous boolean is true.
- err*=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold *sqrt*(*n*)**slamch*(ϵ) for single precision flavors and *sqrt*(*n*)**diamch*(ϵ) for double

precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1/(\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z . Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

err_bnds_comp

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:
 Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{\text{true}_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params*(3) = 0.0), then *err_bnds_comp* is not accessed. If *n_err_bnds* < 3, then at most the first ($:$, *n_err_bnds*) entries are returned.

The first index in *err_bnds_comp*(i , $:$) corresponds to the i -th right-hand side.

The second index in *err_bnds_comp*($:$, *err*) contains the following three fields:

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision flavors.

<i>err=2</i>	<p>"Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold</p> <p>$\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.</p>
<i>err=3</i>	<p>Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold</p> <p>$\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are</p> <p>$1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z.</p> <p>Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.</p>
<i>params</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Output parameter only if the input contains erroneous values, namely, in <i>params(1)</i>, <i>params(2)</i>, <i>params(3)</i>. In such a case, the corresponding elements of <i>params</i> are filled with default values on output.</p>
<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful. The solution to every right-hand side is guaranteed. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

If $0 < info \leq n$: $U(info, info)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = n + j$: The solution corresponding to the j -th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $params(3) = 0.0$, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that $err_bnds_norm(j, 1) = 0.0$ or $err_bnds_comp(j, 1) = 0.0$. See the definition of $err_bnds_norm(, 1)$ and $err_bnds_comp(, 1)$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

?herfs

Refines the solution of a system of linear equations with a complex Hermitian matrix and estimates its error.

Syntax

FORTRAN 77:

```
call cherfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

```
call zherfs( uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call herfs( a, af, ipiv, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine performs an iterative refinement of the solution to a system of linear equations $A^*X = B$ with a complex Hermitian full-storage matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?hetrf](#)
- call the solver routine [?hetrs](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a,af,b,x,work</i>	COMPLEX for <i>cherfs</i> DOUBLE COMPLEX for <i>zherfs</i> . Arrays: <i>a(lda,*)</i> contains the original matrix A , as supplied to ?hetrf . <i>af(ldaf,*)</i> contains the factored matrix A , as returned by ?hetrf . <i>b(ldb,*)</i> contains the right-hand side matrix B . <i>x(ldx,*)</i> contains the solution matrix X . <i>work(*)</i> is a workspace array. The second dimension of <i>a</i> and <i>af</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 2*n)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of <i>af</i> ; $ldaf \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?hetrf .
<i>rwork</i>	REAL for <i>cherfs</i> DOUBLE PRECISION for <i>zherfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr, berr</i>	REAL for <i>cherfs</i> DOUBLE PRECISION for <i>zherfs</i> . Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *herfs* interface are as follows:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>af</i>	Holds the matrix <i>AF</i> of size (n, n) .
<i>ipiv</i>	Holds the vector of length <i>n</i> .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $16n^2$ operations. In addition, each step of iterative refinement involves $24n^2$ operations; the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

The real counterpart of this routine is [?ssyrfs/?dsyrfs](#)

[?herfsx](#)

Uses extra precise iterative refinement to improve the solution to the system of linear equations with a symmetric indefinite matrix A and provides error bounds and backward error estimates.

Syntax

FORTRAN 77:

```
call cherfsx( uplo, equed, n, nrhs, a, lda, af, ldaf, ipiv, s, b, ldb, x, ldx,
             rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work,
             rwork, info )
```

```
call zherfsx( uplo, equed, n, nrhs, a, lda, af, ldaf, ipiv, s, b, ldb, x, ldx,
             rcond, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams, params, work,
             rwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution. In addition to a normwise error bound, the code provides a maximum componentwise error bound, if possible. See comments for `err_bnds_norm` and `err_bnds_comp` for details of the error bounds.

The original system of linear equations may have been equilibrated before calling this routine, as described by the parameters `equed` and `s` below. In this case, the solution and error bounds returned are for the original unequilibrated system.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of <i>A</i> is stored:</p> <p>If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored.</p> <p>If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.</p>
<i>equed</i>	<p>CHARACTER*1. Must be 'N' or 'Y'.</p> <p>Specifies the form of equilibration that was done to <i>A</i> before calling this routine.</p> <p>If <i>equed</i> = 'N', no equilibration was done.</p> <p>If <i>equed</i> = 'Y', both row and column equilibration was done, that is, <i>A</i> has been replaced by $diag(s)*A*diag(s)$. The right-hand side <i>B</i> has been changed accordingly.</p>
<i>n</i>	<p>INTEGER. The number of linear equations; the order of the matrix <i>A</i>; $n \geq 0$.</p>
<i>nrhs</i>	<p>INTEGER. The number of right-hand sides; the number of columns of the matrices <i>B</i> and <i>X</i>; $nrhs \geq 0$.</p>
<i>a, af, b, work</i>	<p>COMPLEX for <code>cherfsx</code> DOUBLE COMPLEX for <code>zherfsx</code>.</p> <p>Arrays: <i>a</i>(<i>lda</i>,*), <i>af</i>(<i>ldaf</i>,*), <i>b</i>(<i>ldb</i>,*), <i>work</i>(*). The array <i>a</i> contains the Hermitian matrix <i>A</i> as specified by <i>uplo</i>. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of <i>a</i> contains the upper triangular part of the matrix <i>A</i> and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of <i>a</i> contains the lower triangular part of the matrix <i>A</i> and the strictly upper triangular part of <i>a</i> is not referenced. The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p>The factored form of the matrix <i>A</i>. The array <i>af</i> contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> from the factorization $A = U*D*U**T$ or $A = L*D*L**T$ as computed by <code>ssytrf</code> for <code>cherfsx</code> or <code>dsytrf</code> for <code>zherfsx</code>.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.</p>

	<i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 2*n)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of <i>af</i> ; $ldaf \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of <i>D</i> as determined by ssytrf for real flavors or dsytrf for complex flavors.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i> . If <i>equet</i> = 'N', <i>s</i> is not accessed. If <i>equet</i> = 'Y', each element of <i>s</i> must be positive. Each element of <i>s</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.
<i>ldb</i>	INTEGER. The first dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$.
<i>x</i>	COMPLEX for cherfsx DOUBLE COMPLEX for zherfsx . Array, DIMENSION (<i>ldx</i> , *). The solution matrix <i>x</i> as computed by ?hetrs
<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>n_err_bnds</i>	INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See err_bnds_norm and err_bnds_comp descriptions in <i>Output Arguments</i> section below.

nparams INTEGER. Specifies the number of parameters set in *params*. If ≤ 0 , the *params* array is never referenced and default values are used.

params REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION *nparams*. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with the default value used for that parameter. Only positions up to *nparams* are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass *nparams* = 0, which prevents the source code from accessing the *params* argument.

params(*la_linrx_itref_i* = 1) : Whether to perform iterative refinement or not. Default: 1.0 (for *cherfsx*), 1.0D+0 (for *zherfsx*).

=0.0 No refinement is performed and no error bounds are computed.

=1.0 Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support DOUBLE PRECISION.

(Other values are reserved for future use.)

params(*la_linrx_ithresh_i* = 2) : Maximum number of residual computations allowed for refinement.

Default 10

Aggressive Set to 100 to permit convergence using approximate factorizations or factorizations other than *LU*. If the factorization uses a technique other than Gaussian elimination, the quarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params(*la_linrx_cwise_i* = 3) : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

rwork REAL for cherfsx
 DOUBLE PRECISION for zherfsx.
 Workspace array, DIMENSION at least $\max(1, 3*n)$.

Output Parameters

x COMPLEX for cherfsx
 DOUBLE COMPLEX for zherfsx.
 The improved solution matrix *x*.

rcond REAL for cherfsx
 DOUBLE PRECISION for zherfsx.
 Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision, in particular, if *rcond* = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

berr REAL for cherfsx
 DOUBLE PRECISION for zherfsx.
 Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of *A* or *B* that makes $x(j)$ an exact solution.

err_bnds_norm REAL for cherfsx
 DOUBLE PRECISION for zherfsx.
 Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:
 Normwise relative error in the *i*-th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in $err_bnds_norm(i, :)$ corresponds to the i -th right-hand side.

The second index in $err_bnds_norm(:, err)$ contains the following three fields:

- $err=1$ "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for `cherfsx` and $\sqrt{n} * dlamch(\epsilon)$ for `zherfsx`.
- $err=2$ "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for `cherfsx` and $\sqrt{n} * dlamch(\epsilon)$ for `zherfsx`. This error bound should only be trusted if the previous boolean is true.
- $err=3$ Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for `cherfsx` and $\sqrt{n} * dlamch(\epsilon)$ for `zherfsx` to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z . Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

err_bnds_comp

REAL for `cherfsx`

DOUBLE PRECISION for `zherfsx`.

Array, DIMENSION ($nrhs, n_err_bnds$). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($params(3) = 0.0$), then `err_bnds_comp` is not accessed. If $n_err_bnds < 3$, then at most the first $(: , n_err_bnds)$ entries are returned.

The first index in `err_bnds_comp(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:, err)` contains the following three fields:

- `err=1` "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for `cherfsx` and $\sqrt{n} * dlamch(\epsilon)$ for `zherfsx`.
- `err=2` "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for `cherfsx` and $\sqrt{n} * dlamch(\epsilon)$ for `zherfsx`. This error bound should only be trusted if the previous boolean is true.
- `err=3` Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for `cherfsx` and $\sqrt{n} * dlamch(\epsilon)$ for `zherfsx` to determine if the error estimate is

"guaranteed". These reciprocal condition numbers are $1/(\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z . Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

params REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Output parameter only if the input contains erroneous values, namely, in *params(1)*, *params(2)*, *params(3)*. In such a case, the corresponding elements of *params* are filled with default values on output.

info INTEGER. If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed.
If *info* = -*i*, the *i*-th parameter had an illegal value.
If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned.
If *info* = $n+j$: The solution corresponding to the *j*-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides *k* with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested *params(3)* = 0.0, then the *j*-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest *j* such that $\text{err_bnds_norm}(j, 1) = 0.0$ or $\text{err_bnds_comp}(j, 1) = 0.0$. See the definition of $\text{err_bnds_norm}(\ ;, 1)$ and $\text{err_bnds_comp}(\ ;, 1)$). To get information about all of the right-hand sides, check *err_bnds_norm* or *err_bnds_comp*.

?sprfs

Refines the solution of a system of linear equations with a packed symmetric matrix and estimates the solution error.

Syntax

FORTRAN 77:

```
call ssprfs( uplo, n, nrhs, ap, AFP, ipiv, b, ldb, x, ldx, ferr, berr, work,
            iwork, info )
```

```
call dsprfs( uplo, n, nrhs, ap, AFP, ipiv, b, ldb, x, ldx, ferr, berr, work,
            iwork, info )
```

```
call csprfs( uplo, n, nrhs, ap, AFP, ipiv, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
```

```
call zsprfs( uplo, n, nrhs, ap, AFP, ipiv, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
```

Fortran 95:

```
call sprfs( ap, AFP, ipiv, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a packed symmetric matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?sptf](#)

- call the solver routine `?sptrs`.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ap,afp,b,x,work</i>	REAL for <i>ssprfs</i> DOUBLE PRECISION for <i>dsprfs</i> COMPLEX for <i>csprfs</i> DOUBLE COMPLEX for <i>zsprfs</i> . Arrays: <i>ap</i> (*) contains the original packed matrix <i>A</i> , as supplied to <code>?sptrf</code> . <i>afp</i> (*) contains the factored packed matrix <i>A</i> , as returned by <code>?sptrf</code> . <i>b</i> (<i>ldb</i> ,*) contains the right-hand side matrix <i>B</i> . <i>x</i> (<i>ldx</i> ,*) contains the solution matrix <i>X</i> . <i>work</i> (*) is a workspace array. The dimension of arrays <i>ap</i> and <i>afp</i> must be at least $\max(1, n(n+1)/2)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by <code>?sptrf</code> .
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>csprfs</i> DOUBLE PRECISION for <i>zsprfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
----------	--

<i>ferr</i> , <i>berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sprfs* interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>afp</i>	Holds the array <i>AF</i> of size $(n*(n+1)/2)$.
<i>ipiv</i>	Holds the vector of length <i>n</i> .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations (for real flavors) or $16n^2$ operations (for complex flavors). In addition, each step of iterative refinement involves $6n^2$ operations (for real flavors) or $24n^2$ operations (for complex flavors); the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n^2$ floating-point operations for real flavors or $8n^2$ for complex flavors.

?hprfs

Refines the solution of a system of linear equations with a packed complex Hermitian matrix and estimates the solution error.

Syntax

FORTRAN 77:

```
call chprfs( uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
```

```
call zhprfs( uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
```

Fortran 95:

```
call hprfs( ap, afp, ipiv, b, x [,uplo] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine performs an iterative refinement of the solution to a system of linear equations $A \cdot X = B$ with a packed complex Hermitian matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

Finally, the routine estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine:

- call the factorization routine [?hptrf](#)
- call the solver routine [?hptrs](#).

Input Parameters

`uplo` CHARACTER*1. Must be 'U' or 'L'.

	If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored. If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ap,afp,b,x,work</i>	COMPLEX for <i>chprfs</i> DOUBLE COMPLEX for <i>zhprfs</i> . Arrays: <i>ap</i> (*) contains the original packed matrix <i>A</i> , as supplied to ?hptrf . <i>afp</i> (*) contains the factored packed matrix <i>A</i> , as returned by ?hptrf . <i>b</i> (<i>ldb</i> ,*) contains the right-hand side matrix <i>B</i> . <i>x</i> (<i>ldx</i> ,*) contains the solution matrix <i>X</i> . <i>work</i> (*) is a workspace array. The dimension of arrays <i>ap</i> and <i>afp</i> must be at least $\max(1, n(n+1)/2)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 2*n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by ?hptrf .
<i>rwork</i>	REAL for <i>chprfs</i> DOUBLE PRECISION for <i>zhprfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>x</i>	The refined solution matrix <i>X</i> .
<i>ferr, berr</i>	REAL for <i>chprfs</i> . DOUBLE PRECISION for <i>zhprfs</i> . Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hprfs` interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>afp</i>	Holds the array <i>AF</i> of size $(n*(n+1)/2)$.
<i>ipiv</i>	Holds the vector of length <i>n</i> .
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

For each right-hand side, computation of the backward error involves a minimum of $16n^2$ operations. In addition, each step of iterative refinement involves $24n^2$ operations; the number of iterations may range from 1 to 5.

Estimating the forward error involves solving a number of systems of linear equations $A*x = b$; the number is usually 4 or 5 and never more than 11. Each solution requires approximately $8n^2$ floating-point operations.

The real counterpart of this routine is [?ssprfs/?dsprfs](#).

?trrfs

Estimates the error in the solution of a system of linear equations with a triangular matrix.

Syntax

FORTRAN 77:

```
call strrfs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, x, ldx, ferr, berr,
work, iwork, info )
```

```
call dtrrfs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, x, ldx, ferr, berr,
work, iwork, info )
```

```
call ctrrfs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, x, ldx, ferr, berr,
work, rwork, info )
```

```
call ztrrfs( uplo, trans, diag, n, nrhs, a, lda, b, ldb, x, ldx, ferr, berr,
work, rwork, info )
```

Fortran 95:

```
call trrfs( a, b, x [,uplo] [,trans] [,diag] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates the errors in the solution to a system of linear equations $A^*X = B$ or $A^T * X = B$ or $A^H * X = B$ with a triangular matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \quad \text{such that } (A + \delta A)x = (b + \delta b).$$

The routine also estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine, call the solver routine [?trtrs](#).

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Indicates whether <i>A</i> is upper or lower triangular:</p> <p>If <i>uplo</i> = 'U', then <i>A</i> is upper triangular.</p> <p>If <i>uplo</i> = 'L', then <i>A</i> is lower triangular.</p>
<i>trans</i>	<p>CHARACTER*1. Must be 'N' or 'T' or 'C'.</p> <p>Indicates the form of the equations:</p> <p>If <i>trans</i> = 'N', the system has the form $A^*X = B$.</p> <p>If <i>trans</i> = 'T', the system has the form $A^T * X = B$.</p> <p>If <i>trans</i> = 'C', the system has the form $A^H * X = B$.</p>
<i>diag</i>	<p>CHARACTER*1. Must be 'N' or 'U'.</p> <p>If <i>diag</i> = 'N', then <i>A</i> is not a unit triangular matrix.</p> <p>If <i>diag</i> = 'U', then <i>A</i> is unit triangular: diagonal elements of <i>A</i> are assumed to be 1 and not referenced in the array <i>a</i>.</p>
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>a, b, x, work</i>	<p>REAL for <i>strrfs</i></p> <p>DOUBLE PRECISION for <i>dtrrfs</i></p> <p>COMPLEX for <i>ctrufs</i></p> <p>DOUBLE COMPLEX for <i>ztrufs</i>.</p> <p>Arrays:</p> <p><i>a(lda, *)</i> contains the upper or lower triangular matrix <i>A</i>, as specified by <i>uplo</i>.</p> <p><i>b(ldb, *)</i> contains the right-hand side matrix <i>B</i>.</p> <p><i>x(ldx, *)</i> contains the solution matrix <i>X</i>.</p> <p><i>work(*)</i> is a workspace array.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.</p>
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.

rwork REAL for `ctrtrfs`
 DOUBLE PRECISION for `ztrtrfs`.
 Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

ferr, berr REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.

info INTEGER. If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trrfs` interface are as follows:

a Holds the matrix *A* of size (n, n) .
b Holds the matrix *B* of size $(n, nrhs)$.
x Holds the matrix *X* of size $(n, nrhs)$.
ferr Holds the vector of length $(nrhs)$.
berr Holds the vector of length $(nrhs)$.
uplo Must be 'U' or 'L'. The default value is 'U'.
trans Must be 'N', 'C', or 'T'. The default value is 'N'.
diag Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations $A*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors or $4n^2$ for complex flavors.

?tprfs

Estimates the error in the solution of a system of linear equations with a packed triangular matrix.

Syntax

FORTRAN 77:

```
call stprfs( uplo, trans, diag, n, nrhs, ap, b, ldb, x, ldx, ferr, berr, work,
            iwork, info )
```

```
call dtprfs( uplo, trans, diag, n, nrhs, ap, b, ldb, x, ldx, ferr, berr, work,
            iwork, info )
```

```
call ctprfs( uplo, trans, diag, n, nrhs, ap, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
```

```
call ztprfs( uplo, trans, diag, n, nrhs, ap, b, ldb, x, ldx, ferr, berr, work,
            rwork, info )
```

Fortran 95:

```
call tprfs( ap, b, x [,uplo] [,trans] [,diag] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates the errors in the solution to a system of linear equations $A^*X = B$ or $A^T * X = B$ or $A^H * X = B$ with a packed triangular matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

The routine also estimates the *component-wise forward error* in the computed solution $\| |x - x_e| \|_\infty / \| |x| \|_\infty$ (here x_e is the exact solution).

Before calling this routine, call the solver routine `?tptrs`.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether <i>A</i> is upper or lower triangular: If <i>uplo</i> = 'U', then <i>A</i> is upper triangular. If <i>uplo</i> = 'L', then <i>A</i> is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$. If <i>trans</i> = 'T', the system has the form $A^T X = B$. If <i>trans</i> = 'C', the system has the form $A^H X = B$.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', <i>A</i> is not a unit triangular matrix. If <i>diag</i> = 'U', <i>A</i> is unit triangular: diagonal elements of <i>A</i> are assumed to be 1 and not referenced in the array <i>ap</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ap, b, x, work</i>	REAL for <i>stprfs</i> DOUBLE PRECISION for <i>dtprfs</i> COMPLEX for <i>ctprfs</i> DOUBLE COMPLEX for <i>ztprfs</i> . Arrays: <i>ap</i> (*) contains the upper or lower triangular matrix <i>A</i> , as specified by <i>uplo</i> . <i>b</i> (<i>ldb</i> ,*) contains the right-hand side matrix <i>B</i> . <i>x</i> (<i>ldx</i> ,*) contains the solution matrix <i>X</i> . <i>work</i> (*) is a workspace array. The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>ctprfs</i> DOUBLE PRECISION for <i>ztprfs</i> .

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>ferr</i> , <i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tprfs` interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations $A*x = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately n^2 floating-point operations for real flavors or $4n^2$ for complex flavors.

?tbrfs

Estimates the error in the solution of a system of linear equations with a triangular band matrix.

Syntax

FORTRAN 77:

```
call stbrfs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, x, ldx, ferr,
berr, work, iwork, info )
```

```
call dtbrfs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, x, ldx, ferr,
berr, work, iwork, info )
```

```
call ctbrfs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

```
call ztbrfs( uplo, trans, diag, n, kd, nrhs, ab, ldab, b, ldb, x, ldx, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call tbrfs( ab, b, x [,uplo] [,trans] [,diag] [,ferr] [,berr] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates the errors in the solution to a system of linear equations $A^*X = B$ or $A^T * X = B$ or $A^H * X = B$ with a triangular band matrix A , with multiple right-hand sides. For each computed solution vector x , the routine computes the *component-wise backward error* β . This error is the smallest relative perturbation in elements of A and b such that x is the exact solution of the perturbed system:

$$|\delta a_{ij}| \leq \beta |a_{ij}|, \quad |\delta b_i| \leq \beta |b_i| \text{ such that } (A + \delta A)x = (b + \delta b).$$

The routine also estimates the *component-wise forward error* in the computed solution $\|x - x_e\|_\infty / \|x\|_\infty$ (here x_e is the exact solution).

Before calling this routine, call the solver routine [?tbtrs](#).

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether <i>A</i> is upper or lower triangular: If <i>uplo</i> = 'U', then <i>A</i> is upper triangular. If <i>uplo</i> = 'L', then <i>A</i> is lower triangular.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', the system has the form $A^*X = B$. If <i>trans</i> = 'T', the system has the form $A^T * X = B$. If <i>trans</i> = 'C', the system has the form $A^H * X = B$.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', <i>A</i> is not a unit triangular matrix. If <i>diag</i> = 'U', <i>A</i> is unit triangular: diagonal elements of <i>A</i> are assumed to be 1 and not referenced in the array <i>ab</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of super-diagonals or sub-diagonals in the matrix <i>A</i> ; $kd \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides; $nrhs \geq 0$.
<i>ab, b, x, work</i>	REAL for <i>stbrfs</i> DOUBLE PRECISION for <i>dtbrfs</i> COMPLEX for <i>ctbrfs</i> DOUBLE COMPLEX for <i>ztbrfs</i> . Arrays: <i>ab(ldab,*)</i> contains the upper or lower triangular matrix <i>A</i> , as specified by <i>uplo</i> , in band storage format. <i>b(l db,*)</i> contains the right-hand side matrix <i>B</i> . <i>x(ldx,*)</i> contains the solution matrix <i>X</i> . <i>work(*)</i> is a workspace array. The second dimension of <i>a</i> must be at least $\max(1, n)$; the second dimension of <i>b</i> and <i>x</i> must be at least $\max(1, nrhs)$. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; $ldab \geq kd + 1$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

<i>ldx</i>	INTEGER. The first dimension of x ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
<i>rwork</i>	REAL for <i>ctbrfs</i> DOUBLE PRECISION for <i>ztbrfs</i> . Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>ferr, berr</i>	REAL for single precision flavors. DOUBLE PRECISION for double precision flavors. Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and backward errors, respectively, for each solution vector.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *tbrfs* interface are as follows:

<i>ab</i>	Holds the array A of size $(kd+1, n)$.
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>diag</i>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The bounds returned in *ferr* are not rigorous, but in practice they almost always overestimate the actual error.

A call to this routine involves, for each right-hand side, solving a number of systems of linear equations $Ax = b$; the number of systems is usually 4 or 5 and never more than 11. Each solution requires approximately $2n*kd$ floating-point operations for real flavors or $8n*kd$ operations for complex flavors.

Routines for Matrix Inversion

It is seldom necessary to compute an explicit inverse of a matrix. In particular, do not attempt to solve a system of equations $Ax = b$ by first computing A^{-1} and then forming the matrix-vector product $x = A^{-1}b$. Call a solver routine instead (see [Routines for Solving Systems of Linear Equations](#)); this is more efficient and more accurate.

However, matrix inversion routines are provided for the rare occasions when an explicit inverse matrix is needed.

?getri

Computes the inverse of an LU-factored general matrix.

Syntax

FORTRAN 77:

```
call sgetri( n, a, lda, ipiv, work, lwork, info )
call dgetri( n, a, lda, ipiv, work, lwork, info )
call cgetri( n, a, lda, ipiv, work, lwork, info )
call zgetri( n, a, lda, ipiv, work, lwork, info )
```

Fortran 95:

```
call getri( a, ipiv [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes the inverse $\text{inv}(A)$ of a general matrix A . Before calling this routine, call [?getrf](#) to factorize A .

Input Parameters

<i>n</i>	INTEGER. The order of the matrix <i>A</i> ; $n \geq 0$.
<i>a</i> , <i>work</i>	REAL for <code>sgetri</code> DOUBLE PRECISION for <code>dgetri</code> COMPLEX for <code>cgetri</code> DOUBLE COMPLEX for <code>zgetri</code> . Arrays: <i>a</i> (<i>lda</i> ,*), <i>work</i> (*). <i>a</i> (<i>lda</i> ,*) contains the factorization of the matrix <i>A</i> , as returned by <code>?getrf</code> : $A = P*L*U$. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array of dimension at least $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by <code>?getrf</code> .
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; $lwork \geq n$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> .

See *Application Notes* below for the suggested value of *lwork*.

Output Parameters

<i>a</i>	Overwritten by the <i>n</i> -by- <i>n</i> matrix $\text{inv}(A)$.
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the <i>i</i> -th diagonal element of the factor <i>U</i> is zero, <i>U</i> is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `getri` interface are as follows:

`a` Holds the matrix A of size (n, n) .
`ipiv` Holds the vector of length n .

Application Notes

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed inverse X satisfies the following error bound:

$$|XA - I| \leq c(n)\epsilon |X| |P| |L| |U|,$$

where $c(n)$ is a modest linear function of n ; ϵ is the machine precision; I denotes the identity matrix; P , L , and U are the factors of the matrix factorization $A = P * L * U$.

The total number of floating-point operations is approximately $(4/3)n^3$ for real flavors and $(16/3)n^3$ for complex flavors.

?potri

Computes the inverse of a symmetric (Hermitian) positive-definite matrix.

Syntax

FORTRAN 77:

```
call spotri( uplo, n, a, lda, info )
call dpotri( uplo, n, a, lda, info )
call cpotri( uplo, n, a, lda, info )
call zpotri( uplo, n, a, lda, info )
```

Fortran 95:

```
call potri( a [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the inverse $\text{inv}(A)$ of a symmetric positive definite or, for complex flavors, Hermitian positive-definite matrix A . Before calling this routine, call `?potrf` to factorize A .

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <code>uplo = 'U'</code> , then A is upper triangular. If <code>uplo = 'L'</code> , then A is lower triangular.
<code>n</code>	INTEGER. The order of the matrix A ; $n \geq 0$.
<code>a</code>	REAL for <code>spotri</code> DOUBLE PRECISION for <code>dpotri</code> COMPLEX for <code>cpotri</code> DOUBLE COMPLEX for <code>zpotri</code> . Array <code>a(lda,*)</code> . Contains the factorization of the matrix A , as returned by <code>?potrf</code> . The second dimension of <code>a</code> must be at least $\max(1, n)$.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, n)$.

Output Parameters

a Overwritten by the n -by- n matrix `inv(A)`.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, the *i*-th diagonal element of the Cholesky factor (and therefore the factor itself) is zero, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `potri` interface are as follows:

a Holds the matrix *A* of size (n, n) .

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse x satisfies the following error bounds:

$$\|XA - I\|_2 \leq c(n)\epsilon\kappa_2(A), \quad \|AX - I\|_2 \leq c(n)\epsilon\kappa_2(A),$$

where $c(n)$ is a modest linear function of n , and ϵ is the machine precision; I denotes the identity matrix.

The 2-norm $\|A\|_2$ of a matrix A is defined by $\|A\|_2 = \max_{x \cdot x=1} (Ax \cdot Ax)^{1/2}$, and the condition number $\kappa_2(A)$ is defined by $\kappa_2(A) = \|A\|_2 \|A^{-1}\|_2$.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

?pftri

Computes the inverse of a symmetric (Hermitian) positive-definite matrix in RFP format using the Cholesky factorization.

Syntax

FORTRAN 77:

```
call spftri( transr, uplo, n, a, info )
call dpftri( transr, uplo, n, a, info )
call cpftri( transr, uplo, n, a, info )
call zpftri( transr, uplo, n, a, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes the inverse $\text{inv}(A)$ of a symmetric positive definite or, for complex data, Hermitian positive-definite matrix A using the Cholesky factorization:

$$\begin{array}{ll} A = U^T * U \text{ for real data, } A = U^H * U \text{ for complex data} & \text{if } uplo = 'U' \\ A = L * L^T \text{ for real data, } A = L * L^H \text{ for complex data} & \text{if } uplo = 'L' \end{array}$$

Before calling this routine, call [?pfturf](#) to factorize A .

The matrix A is in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

<i>transr</i>	CHARACTER*1. Must be 'N', 'T' (for real data) or 'C' (for complex data). If <i>transr</i> = 'N', the Normal <i>transr</i> of RFP A is stored. If <i>transr</i> = 'T', the Transpose <i>transr</i> of RFP A is stored. If <i>transr</i> = 'C', the Conjugate-Transpose <i>transr</i> of RFP A is stored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of the RFP matrix A is stored:

If *uplo* = 'U', the array *a* stores the upper triangular part of the matrix *A*.

If *uplo* = 'L', the array *a* stores the lower triangular part of the matrix *A*.

n INTEGER. The order of the matrix *A*; $n \geq 0$.

a REAL for *spftri*
 DOUBLE PRECISION for *dpftri*
 COMPLEX for *cpftri*
 DOUBLE COMPLEX for *zpftri*.
 Array, DIMENSION ($n*(n+1)/2$). The array *a* contains the matrix *A* in the RFP format.

Output Parameters

a The symmetric/Hermitian inverse of the original matrix in the same storage format.

info INTEGER. If *info*=0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, the (*i*,*i*) element of the factor *U* or *L* is zero, and the inverse could not be computed.

?pptri

Computes the inverse of a packed symmetric (Hermitian) positive-definite matrix

Syntax

FORTRAN 77:

```
call spptri( uplo, n, ap, info )
```

```
call dpptri( uplo, n, ap, info )
```

```
call cpptri( uplo, n, ap, info )
```

```
call zpptri( uplo, n, ap, info )
```

Fortran 95:

```
call pptri( ap [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the inverse $\text{inv}(A)$ of a symmetric positive definite or, for complex flavors, Hermitian positive-definite matrix A in *packed* form. Before calling this routine, call [?pptrf](#) to factorize A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular factor is stored in <i>ap</i> : If <i>uplo</i> = 'U', then the upper triangular factor is stored. If <i>uplo</i> = 'L', then the lower triangular factor is stored.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>ap</i>	REAL for <code>spptri</code> DOUBLE PRECISION for <code>dpptri</code> COMPLEX for <code>cpptri</code> DOUBLE COMPLEX for <code>zpptri</code> . Array, DIMENSION at least $\max(1, n(n+1)/2)$. Contains the factorization of the packed matrix A , as returned by ?pptrf . The dimension <i>ap</i> must be at least $\max(1, n(n+1)/2)$.

Output Parameters

<i>ap</i>	Overwritten by the packed n -by- n matrix $\text{inv}(A)$.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = $-i$, the i -th parameter had an illegal value. If <i>info</i> = i , the i -th diagonal element of the Cholesky factor (and therefore the factor itself) is zero, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pptri` interface are as follows:

`ap` Holds the array `A` of size $(n*(n+1)/2)$.
`uplo` Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse x satisfies the following error bounds:

$$\|XA - I\|_2 \leq c(n)\epsilon\kappa_2(A), \quad \|AX - I\|_2 \leq c(n)\epsilon\kappa_2(A),$$

where $c(n)$ is a modest linear function of n , and ϵ is the machine precision; I denotes the identity matrix.

The 2-norm $\|A\|_2$ of a matrix A is defined by $\|A\|_2 = \max_{x \cdot x=1} (Ax \cdot Ax)^{1/2}$, and the condition number $\kappa_2(A)$ is defined by $\kappa_2(A) = \|A\|_2 \|A^{-1}\|_2$.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

?sytri

Computes the inverse of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssytri( uplo, n, a, lda, ipiv, work, info )
call dsytri( uplo, n, a, lda, ipiv, work, info )
call csytri( uplo, n, a, lda, ipiv, work, info )
call zsytri( uplo, n, a, lda, ipiv, work, info )
```

Fortran 95:

```
call sytri( a, ipiv [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the inverse $\text{inv}(A)$ of a symmetric matrix A . Before calling this routine, call `?sytrf` to factorize A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the array a stores the Bunch-Kaufman factorization $A = P*U*D*U^T*P^T$. If <i>uplo</i> = 'L', the array a stores the Bunch-Kaufman factorization $A = P*L*D*L^T*P^T$.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a, work</i>	REAL for <code>ssytri</code> DOUBLE PRECISION for <code>dsytri</code> COMPLEX for <code>csytri</code> DOUBLE COMPLEX for <code>zsytri</code> . Arrays: $a(lda, *)$ contains the factorization of the matrix A , as returned by <code>?sytrf</code> . The second dimension of a must be at least $\max(1, n)$. $work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 2*n)$.
<i>lda</i>	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by <code>?sytrf</code> .

Output Parameters

<i>a</i>	Overwritten by the n -by- n matrix $\text{inv}(A)$.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - i , the i -th parameter had an illegal value. If <i>info</i> = i , the i -th diagonal element of D is zero, D is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sytri` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse x satisfies the following error bounds:

$$|D^*U^T*P^T*X*P*U - I| \leq c(n)\epsilon(|D||U^T|P^T|X|P|U| + |D||D^{-1}|)$$

for `uplo = 'U'`, and

$$|D^*L^T*P^T*X*P*L - I| \leq c(n)\epsilon(|D||L^T|P^T|X|P*L| + |D||D^{-1}|)$$

for `uplo = 'L'`. Here $c(n)$ is a modest linear function of n , and ϵ is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

?hetri

Computes the inverse of a complex Hermitian matrix.

Syntax

FORTRAN 77:

```
call chetri( uplo, n, a, lda, ipiv, work, info )
call zhetri( uplo, n, a, lda, ipiv, work, info )
```

Fortran 95:

```
call hetri( a, ipiv [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the inverse $\text{inv}(A)$ of a complex Hermitian matrix A . Before calling this routine, call `?hetrf` to factorize A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates how the input matrix A has been factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the Bunch-Kaufman factorization $A = P*U*D*U^H*P^T$. If <i>uplo</i> = 'L', the array <i>a</i> stores the Bunch-Kaufman factorization $A = P*L*D*L^H*P^T$.
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a, work</i>	COMPLEX for <code>chetri</code> DOUBLE COMPLEX for <code>zhetri</code> . Arrays: <i>a</i> (<i>lda</i> ,*) contains the factorization of the matrix A , as returned by <code>?hetrf</code> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The <i>ipiv</i> array, as returned by <code>?hetrf</code> .

Output Parameters

<i>a</i>	Overwritten by the n -by- n matrix $\text{inv}(A)$.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the <i>i</i> -th diagonal element of D is zero, D is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetri` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse x satisfies the following error bounds:

$$|D^*U^H*P^T*X*P*U - I| \leq c(n)\epsilon(|D||U^H|P^T|X|P|U| + |D||D^{-1}|)$$

for `uplo = 'U'`, and

$$|D^*L^H*P^T*X*P*L - I| \leq c(n)\epsilon(|D||L^H|P^T|X|P*L| + |D||D^{-1}|)$$

for `uplo = 'L'`. Here $c(n)$ is a modest linear function of n , and ϵ is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

The real counterpart of this routine is [?sytri](#).

?sptri

Computes the inverse of a symmetric matrix using packed storage.

Syntax

FORTRAN 77:

```
call ssptri( uplo, n, ap, ipiv, work, info )
call dsptri( uplo, n, ap, ipiv, work, info )
call csptri( uplo, n, ap, ipiv, work, info )
call zsptri( uplo, n, ap, ipiv, work, info )
```

Fortran 95:

```
call sptri( ap, ipiv [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the inverse $\text{inv}(A)$ of a packed symmetric matrix A . Before calling this routine, call `?sptrf` to factorize A .

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates how the input matrix A has been factored:
If *uplo* = 'U', the array *ap* stores the Bunch-Kaufman factorization $A = P*U*D*U^T*P^T$.
If *uplo* = 'L', the array *ap* stores the Bunch-Kaufman factorization $A = P*L*D*L^T*P^T$.

n INTEGER. The order of the matrix A ; $n \geq 0$.

ap, work REAL for `ssptri`
DOUBLE PRECISION for `dsptri`
COMPLEX for `csptri`
DOUBLE COMPLEX for `zsptri`.
Arrays:
ap(*) contains the factorization of the matrix A , as returned by `?sptrf`.
The dimension of *ap* must be at least $\max(1, n(n+1)/2)$.
work(*) is a workspace array.
The dimension of *work* must be at least $\max(1, n)$.

ipiv INTEGER.
Array, DIMENSION at least $\max(1, n)$. The *ipiv* array, as returned by `?sptrf`.

Output Parameters

ap Overwritten by the n -by- n matrix $\text{inv}(A)$ in packed form.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = $-i$, the i -th parameter had an illegal value.

If $info = i$, the i -th diagonal element of D is zero, D is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sptri` interface are as follows:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse X satisfies the following error bounds:

$$|D*U^T*P^T*X*P*U - I| \leq c(n)\epsilon(|D||U^T|P^T|X|P|U| + |D||D^{-1}|)$$

for `uplo = 'U'`, and

$$|D*L^T*P^T*X*P*L - I| \leq c(n)\epsilon(|D||L^T|P^T|X|P|L| + |D||D^{-1}|)$$

for `uplo = 'L'`. Here $c(n)$ is a modest linear function of n , and ϵ is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

?hptri

Computes the inverse of a complex Hermitian matrix using packed storage.

Syntax

FORTRAN 77:

```
call chptri( uplo, n, ap, ipiv, work, info )
call zhptri( uplo, n, ap, ipiv, work, info )
```

Fortran 95:

```
call hptri( ap, ipiv [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the inverse $\text{inv}(A)$ of a complex Hermitian matrix A using packed storage. Before calling this routine, call `?hptrf` to factorize A .

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates how the input matrix A has been factored:
If *uplo* = 'U', the array *ap* stores the packed Bunch-Kaufman factorization $A = P*U*D*U^H*P^T$.
If *uplo* = 'L', the array *ap* stores the packed Bunch-Kaufman factorization $A = P*L*D*L^H*P^T$.

n INTEGER. The order of the matrix A ; $n \geq 0$.

ap, work COMPLEX for `chptri`
DOUBLE COMPLEX for `zhptri`.
Arrays:
ap(*) contains the factorization of the matrix A , as returned by `?hptrf`.
The dimension of *ap* must be at least $\max(1, n(n+1)/2)$.
work(*) is a workspace array.
The dimension of *work* must be at least $\max(1, n)$.

ipiv INTEGER.
Array, DIMENSION at least $\max(1, n)$.
The *ipiv* array, as returned by `?hptrf`.

Output Parameters

ap Overwritten by the n -by- n matrix $\text{inv}(A)$.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.
If *info* = *i*, the *i*-th diagonal element of D is zero, D is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hptri` interface are as follows:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>ipiv</code>	Holds the vector of length n .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed inverse x satisfies the following error bounds:

$$|D*U^H*P^T*X*P*U - I| \leq c(n)\epsilon(|D||U^H|P^T|X|P|U| + |D||D^{-1}|)$$

for `uplo` = 'U', and

$$|D*L^H*P^T*X*P*L - I| \leq c(n)\epsilon(|D||L^H|P^T|X|P|L| + |D||D^{-1}|)$$

for `uplo` = 'L'. Here $c(n)$ is a modest linear function of n , and ϵ is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(2/3)n^3$ for real flavors and $(8/3)n^3$ for complex flavors.

The real counterpart of this routine is `?sptri`.

?trtri

Computes the inverse of a triangular matrix.

Syntax

FORTRAN 77:

```
call strtri( uplo, diag, n, a, lda, info )
call dtrtri( uplo, diag, n, a, lda, info )
call ctrtri( uplo, diag, n, a, lda, info )
call ztrtri( uplo, diag, n, a, lda, info )
```

Fortran 95:

```
call trtri( a [,uplo] [,diag] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the inverse $\text{inv}(A)$ of a triangular matrix A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If <i>uplo</i> = 'U', then A is upper triangular. If <i>uplo</i> = 'L', then A is lower triangular.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array a .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a</i>	REAL for <code>strtri</code> DOUBLE PRECISION for <code>dtrtri</code> COMPLEX for <code>ctrtri</code> DOUBLE COMPLEX for <code>ztrtri</code> . Array: DIMENSION (, *). Contains the matrix A . The second dimension of a must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.

Output Parameters

<i>a</i>	Overwritten by the n -by- n matrix $\text{inv}(A)$.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = $-i$, the i -th parameter had an illegal value. If <i>info</i> = i , the i -th diagonal element of A is zero, A is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trtri` interface are as follows:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>diag</code>	Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed inverse x satisfies the following error bounds:

$$|XA - I| \leq c(n)\epsilon |X| |A|$$

$$|XA - I| \leq c(n)\epsilon |A^{-1}| |A| |X|,$$

where $c(n)$ is a modest linear function of n ; ϵ is the machine precision; I denotes the identity matrix.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors and $(4/3)n^3$ for complex flavors.

?tftri

Computes the inverse of a triangular matrix stored in the Rectangular Full Packed (RFP) format.

Syntax

FORTRAN 77:

```
call stftri( transr, uplo, diag, n, a, info )
call dtftri( transr, uplo, diag, n, a, info )
call ctftri( transr, uplo, diag, n, a, info )
call ztftri( transr, uplo, diag, n, a, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

Computes the inverse of a triangular matrix A stored in the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

This is the block version of the algorithm, calling Level 3 BLAS.

Input Parameters

<i>transr</i>	CHARACTER*1. Must be 'N', 'T' (for real data) or 'C' (for complex data). If <i>transr</i> = 'N', the Normal <i>transr</i> of RFP A is stored. If <i>transr</i> = 'T', the Transpose <i>transr</i> of RFP A is stored. If <i>transr</i> = 'C', the Conjugate-Transpose <i>transr</i> of RFP A is stored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of RFP A is stored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the matrix A . If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the matrix A .
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If <i>diag</i> = 'N', then A is not a unit triangular matrix. If <i>diag</i> = 'U', A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array <i>a</i> .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.
<i>a</i>	REAL for <code>stftri</code> DOUBLE PRECISION for <code>dtftri</code> COMPLEX for <code>ctftri</code> DOUBLE COMPLEX for <code>ztftri</code> . Array, DIMENSION $(n*(n+1)/2)$. The array <i>a</i> contains the matrix A in the RFP format.

Output Parameters

<i>a</i>	The (triangular) inverse of the original matrix in the same storage format.
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.
If $info = i$, $A(i, i)$ is exactly zero. The triangular matrix is singular and its inverse cannot be computed.

?tptri

Computes the inverse of a triangular matrix using packed storage.

Syntax

FORTRAN 77:

```
call stptri( uplo, diag, n, ap, info )
call dtptri( uplo, diag, n, ap, info )
call ctptri( uplo, diag, n, ap, info )
call ztptri( uplo, diag, n, ap, info )
```

Fortran 95:

```
call tptri( ap [,uplo] [,diag] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes the inverse $inv(A)$ of a packed triangular matrix A .

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether A is upper or lower triangular: If $uplo = 'U'$, then A is upper triangular. If $uplo = 'L'$, then A is lower triangular.
<i>diag</i>	CHARACTER*1. Must be 'N' or 'U'. If $diag = 'N'$, then A is not a unit triangular matrix. If $diag = 'U'$, A is unit triangular: diagonal elements of A are assumed to be 1 and not referenced in the array ap .
<i>n</i>	INTEGER. The order of the matrix A ; $n \geq 0$.

ap REAL for `stptri`
 DOUBLE PRECISION for `dtptri`
 COMPLEX for `ctptri`
 DOUBLE COMPLEX for `ztptri`.
 Array, DIMENSION at least $\max(1, n(n+1)/2)$.
 Contains the packed triangular matrix *A*.

Output Parameters

ap Overwritten by the packed n -by- n matrix $\text{inv}(A)$.
info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, the *i*-th diagonal element of *A* is zero, *A* is singular, and the inversion could not be completed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tptri` interface are as follows:

ap Holds the array *A* of size $(n*(n+1)/2)$.
uplo Must be 'U' or 'L'. The default value is 'U'.
diag Must be 'N' or 'U'. The default value is 'N'.

Application Notes

The computed inverse *X* satisfies the following error bounds:

$$|XA - I| \leq c(n)\epsilon |X| |A|$$

$$|X - A^{-1}| \leq c(n)\epsilon |A^{-1}| |A| |X|,$$

where $c(n)$ is a modest linear function of n ; ϵ is the machine precision; *I* denotes the identity matrix.

The total number of floating-point operations is approximately $(1/3)n^3$ for real flavors and $(4/3)n^3$ for complex flavors.

Routines for Matrix Equilibration

Routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

?geequ

Computes row and column scaling factors intended to equilibrate a general matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call sgeequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call dgeequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call cgeequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call zgeequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
```

Fortran 95:

```
call geequ( a, r, c [,rowcnd] [,colcnd] [,amax] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes row and column scalings intended to equilibrate an m -by- n matrix A and reduce its condition number. The output array r returns the row scale factors and the array c the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij}=r(i)*a_{ij}*c(j)$ have absolute value 1.

See [?laqge](#) auxiliary function that uses scaling factors computed by `?geequ`.

Input Parameters

m INTEGER. The number of rows of the matrix A ; $m \geq 0$.

n INTEGER. The number of columns of the matrix A ; $n \geq 0$.

a REAL for *sggequ*
 DOUBLE PRECISION for *dgeequ*
 COMPLEX for *cgeequ*
 DOUBLE COMPLEX for *zgeequ*.
 Array: DIMENSION (*lda*, *).
 Contains the *m*-by-*n* matrix *A* whose equilibration factors are to be computed.
 The second dimension of *a* must be at least $\max(1, n)$.

lda INTEGER. The leading dimension of *a*; $lda \geq \max(1, m)$.

Output Parameters

r, c REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Arrays: *r*(*m*), *c*(*n*).
 If *info* = 0, or *info* > *m*, the array *r* contains the row scale factors of the matrix *A*.
 If *info* = 0, the array *c* contains the column scale factors of the matrix *A*.

rowcnd REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 If *info* = 0 or *info* > *m*, *rowcnd* contains the ratio of the smallest *r*(*i*) to the largest *r*(*i*).

colcnd REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 If *info* = 0, *colcnd* contains the ratio of the smallest *c*(*i*) to the largest *c*(*i*).

amax REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Absolute value of the largest element of the matrix *A*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i* and
i ≤ *m*, the *i*-th row of *A* is exactly zero;
i > *m*, the (*i*-*m*)th column of *A* is exactly zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geequ` interface are as follows:

<code>a</code>	Holds the matrix A of size (m, n) .
<code>r</code>	Holds the vector of length (m) .
<code>c</code>	Holds the vector of length n .

Application Notes

All the components of `r` and `c` are restricted to be between `SMLNUM` = smallest safe number and `BIGNUM`= largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

If `rowcnd` ≥ 0.1 and `amax` is neither too large nor too small, it is not worth scaling by `r`.

If `colcnd` ≥ 0.1 , it is not worth scaling by `c`.

If `amax` is very close to overflow or very close to underflow, the matrix A should be scaled.

?geequ

Computes row and column scaling factors restricted to a power of radix to equilibrate a general matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call sgeequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call dgeequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call cgeequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
call zgeequ( m, n, a, lda, r, c, rowcnd, colcnd, amax, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes row and column scalings intended to equilibrate an m -by- n general matrix A and reduce its condition number. The output array r returns the row scale factors and the array c - the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b(ij)=r(i)*a(ij)*c(j)$ have an absolute value of at most the radix.

$r(i)$ and $c(j)$ are restricted to be a power of the radix between `SMLNUM` = smallest safe number and `BIGNUM` = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of a but works well in practice.

This routine differs from `?geequ` by restricting the scaling factors to a power of the radix. Except for over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer equal to approximately 1 but lie between $\sqrt{\text{radix}}$ and $1/\sqrt{\text{radix}}$.

Input Parameters

m	INTEGER. The number of rows of the matrix A ; $m \geq 0$.
n	INTEGER. The number of columns of the matrix A ; $n \geq 0$.
a	REAL for <code>sgeequb</code> DOUBLE PRECISION for <code>dgeequb</code> COMPLEX for <code>cgeequb</code> DOUBLE COMPLEX for <code>zgeequb</code> . Array: DIMENSION ($lda, *$). Contains the m -by- n matrix A whose equilibration factors are to be computed. The second dimension of a must be at least $\max(1, n)$.
lda	INTEGER. The first dimension of a ; $lda \geq \max(1, m)$.

Output Parameters

r, c	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: $r(m), c(n)$.
--------	---

	If $info = 0$, or $info > m$, the array r contains the row scale factors for the matrix A .
	If $info = 0$, the array c contains the column scale factors for the matrix A .
$rowcnd$	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If $info = 0$ or $info > m$, $rowcnd$ contains the ratio of the smallest $r(i)$ to the largest $r(i)$. If $rowcnd \geq 0.1$, and $amax$ is neither too large nor too small, it is not worth scaling by r .
$colcnd$	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If $info = 0$, $colcnd$ contains the ratio of the smallest $c(i)$ to the largest $c(i)$. If $colcnd \geq 0.1$, it is not worth scaling by c .
$amax$	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Absolute value of the largest element of the matrix A . If $amax$ is very close to overflow or very close to underflow, the matrix should be scaled.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$ and $i \leq m$, the i -th row of A is exactly zero; $i > m$, the $(i-m)$ -th column of A is exactly zero.

?gbequ

Computes row and column scaling factors intended to equilibrate a banded matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call sgbequ( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )  
call dgbequ( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
```

```
call cgbequ( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
call zgbequ( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
```

Fortran 95:

```
call gbequ( ab, r, c [,kl] [,rowcnd] [,colcnd] [,amax] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes row and column scalings intended to equilibrate an m -by- n band matrix A and reduce its condition number. The output array r returns the row scale factors and the array c the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij}=r(i)*a_{ij}*c(j)$ have absolute value 1.

See [?laqgb](#) auxiliary function that uses scaling factors computed by `?gbequ`.

Input Parameters

m	INTEGER. The number of rows of the matrix A ; $m \geq 0$.
n	INTEGER. The number of columns of the matrix A ; $n \geq 0$.
kl	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
ku	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
ab	REAL for <code>sgbequ</code> DOUBLE PRECISION for <code>dgbequ</code> COMPLEX for <code>cgbequ</code> DOUBLE COMPLEX for <code>zgbequ</code> . Array, DIMENSION ($ldab$, *). Contains the original band matrix A stored in rows from 1 to $kl + ku + 1$. The second dimension of ab must be at least $\max(1, n)$.
$ldab$	INTEGER. The leading dimension of ab ; $ldab \geq kl + ku + 1$.

Output Parameters

r, c	REAL for single precision flavors
--------	-----------------------------------

	DOUBLE PRECISION for double precision flavors. Arrays: $r(m), c(n)$. If $info = 0$, or $info > m$, the array r contains the row scale factors of the matrix A . If $info = 0$, the array c contains the column scale factors of the matrix A .
<i>rowcnd</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If $info = 0$ or $info > m$, <i>rowcnd</i> contains the ratio of the smallest $r(i)$ to the largest $r(i)$.
<i>colcnd</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If $info = 0$, <i>colcnd</i> contains the ratio of the smallest $c(i)$ to the largest $c(i)$.
<i>amax</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Absolute value of the largest element of the matrix A .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$ and $i \leq m$, the i -th row of A is exactly zero; $i > m$, the $(i-m)$ th column of A is exactly zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbequ` interface are as follows:

<i>ab</i>	Holds the array A of size $(kl+ku+1, n)$.
<i>r</i>	Holds the vector of length (m) .
<i>c</i>	Holds the vector of length n .
<i>kl</i>	If omitted, assumed $kl = ku$.
<i>ku</i>	Restored as $ku = lda-kl-1$.

Application Notes

All the components of r and c are restricted to be between $SMLNUM$ = smallest safe number and $BIGNUM$ = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

If $rowcnd \geq 0.1$ and $amax$ is neither too large nor too small, it is not worth scaling by r .

If $colcnd \geq 0.1$, it is not worth scaling by c .

If $amax$ is very close to overflow or very close to underflow, the matrix A should be scaled.

?gbequb

Computes row and column scaling factors restricted to a power of radix to equilibrate a banded matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call sgbequb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
call dgbequb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
call cgbequb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
call zgbequb( m, n, kl, ku, ab, ldab, r, c, rowcnd, colcnd, amax, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes row and column scalings intended to equilibrate an m -by- n banded matrix A and reduce its condition number. The output array r returns the row scale factors and the array c - the column scale factors. These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b(ij) = r(i) * a(ij) * c(j)$ have an absolute value of at most the radix.

$r(i)$ and $c(j)$ are restricted to be a power of the radix between $SMLNUM$ = smallest safe number and $BIGNUM$ = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of a but works well in practice.

This routine differs from `?gbequ` by restricting the scaling factors to a power of the radix. Except for over- and underflow, scaling by these factors introduces no additional rounding errors. However, the scaled entries' magnitudes are no longer equal to approximately 1 but lie between $\sqrt{\text{radix}}$ and $1/\sqrt{\text{radix}}$.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ; $m \geq 0$.
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of <i>A</i> ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of <i>A</i> ; $ku \geq 0$.
<i>ab</i>	REAL for <code>sgbequ</code> DOUBLE PRECISION for <code>dgbequ</code> COMPLEX for <code>cgbequ</code> DOUBLE COMPLEX for <code>zgbequ</code> . Array: DIMENSION (<i>ldab</i> , *). Contains the original banded matrix <i>A</i> stored in rows from 1 to <i>kl</i> + <i>ku</i> + 1. The <i>j</i> -th column of <i>A</i> is stored in the <i>j</i> -th column of the array <i>ab</i> as follows: $ab(ku+1+i-j, j) = a(i, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$. The second dimension of <i>ab</i> must be at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The first dimension of <i>a</i> ; $ldab \geq \max(1, m)$.

Output Parameters

<i>r, c</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: <i>r</i> (<i>m</i>), <i>c</i> (<i>n</i>). If <i>info</i> = 0, or <i>info</i> > <i>m</i> , the array <i>r</i> contains the row scale factors for the matrix <i>A</i> . If <i>info</i> = 0, the array <i>c</i> contains the column scale factors for the matrix <i>A</i> .
<i>rowcnd</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

	If $info = 0$ or $info > m$, $rowcnd$ contains the ratio of the smallest $r(i)$ to the largest $r(i)$. If $rowcnd \geq 0.1$, and $amax$ is neither too large nor too small, it is not worth scaling by r .
$colcnd$	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If $info = 0$, $colcnd$ contains the ratio of the smallest $c(i)$ to the largest $c(i)$. If $colcnd \geq 0.1$, it is not worth scaling by c .
$amax$	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Absolute value of the largest element of the matrix A . If $amax$ is very close to overflow or underflow, the matrix should be scaled.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, the i -th diagonal element of A is nonpositive. $i \leq m$, the i -th row of A is exactly zero; $i > m$, the $(i-m)$ -th column of A is exactly zero.

?poequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call spoequ( n, a, lda, s, scnd, amax, info )
call dpoequ( n, a, lda, s, scnd, amax, info )
call cpoequ( n, a, lda, s, scnd, amax, info )
call zpoequ( n, a, lda, s, scnd, amax, info )
```

Fortran 95:

```
call poequ( a, s [,scnd] [,amax] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive-definite matrix A and reduce its condition number (with respect to the two-norm). The output array s returns scale factors computed as

$$s(i) = \frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled matrix B with elements $b_{ij}=s(i)*a_{ij}*s(j)$ has diagonal elements equal to 1.

This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

See `?laqsy` auxiliary function that uses scaling factors computed by `?poequ`.

Input Parameters

n	INTEGER. The order of the matrix A ; $n \geq 0$.
a	REAL for <code>spoequ</code> DOUBLE PRECISION for <code>dpoequ</code> COMPLEX for <code>cpoequ</code> DOUBLE COMPLEX for <code>zpoequ</code> . Array: DIMENSION ($lda, *$). Contains the n -by- n symmetric or Hermitian positive definite matrix A whose scaling factors are to be computed. Only the diagonal elements of A are referenced. The second dimension of a must be at least $\max(1, n)$.
lda	INTEGER. The leading dimension of a ; $lda \geq \max(1, n)$.

Output Parameters

s	REAL for single precision flavors
-----	-----------------------------------

DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION (n).
 If $info = 0$, the array s contains the scale factors for A .

scond REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 If $info = 0$, *scond* contains the ratio of the smallest $s(i)$ to the largest $s(i)$.

amax REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Absolute value of the largest element of the matrix A .

info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info = i$, the i -th diagonal element of A is nonpositive.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `poequ` interface are as follows:

a Holds the matrix A of size (n, n) .
 s Holds the vector of length n .

Application Notes

If $scond \geq 0.1$ and $amax$ is neither too large nor too small, it is not worth scaling by s .

If $amax$ is very close to overflow or very close to underflow, the matrix A should be scaled.

?poequb

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call spoequb( n, a, lda, s, scond, amax, info )
call dpoequb( n, a, lda, s, scond, amax, info )
call cpoequb( n, a, lda, s, scond, amax, info )
call zpoequb( n, a, lda, s, scond, amax, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive-definite matrix A and reduce its condition number (with respect to the two-norm).

These factors are chosen so that the scaled matrix B with elements $b(i,j)=s(i)*a(i,j)*s(j)$ has diagonal elements equal to 1. $s(i)$ is a power of two nearest to, but not exceeding $1/\sqrt{A(i,i)}$.

This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

Input Parameters

n	INTEGER. The order of the matrix A ; $n \geq 0$.
a	REAL for <code>spoequb</code> DOUBLE PRECISION for <code>dpoequb</code> COMPLEX for <code>cpoequb</code> DOUBLE COMPLEX for <code>zpoequb</code> . Array: DIMENSION ($lda, *$). Contains the n -by- n symmetric or Hermitian positive definite matrix A whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

The second dimension of a must be at least $\max(1, n)$.

lda INTEGER. The first dimension of a ; $lda \geq \max(1, m)$.

Output Parameters

s REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Array, DIMENSION (n).
If $info = 0$, the array s contains the scale factors for A .

scond REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
If $info = 0$, $scond$ contains the ratio of the smallest $s(i)$ to the largest $s(i)$. If $scond \geq 0.1$, and $amax$ is neither too large nor too small, it is not worth scaling by s .

amax REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Absolute value of the largest element of the matrix A . If $amax$ is very close to overflow or underflow, the matrix should be scaled.

info INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.
If $info = i$, the i -th diagonal element of A is nonpositive.

?ppequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite matrix in packed storage and reduce its condition number.

Syntax

FORTRAN 77:

```
call sppequ( uplo, n, ap, s, scnd, amax, info )
call dppequ( uplo, n, ap, s, scnd, amax, info )
call cppequ( uplo, n, ap, s, scnd, amax, info )
call zppequ( uplo, n, ap, s, scnd, amax, info )
```

Fortran 95:

```
call ppequ( ap, s [,scond] [,amax] [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). The output array s returns scale factors computed as

$$s(i) = \frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled matrix B with elements $b_{ij}=s(i)*a_{ij}*s(j)$ has diagonal elements equal to 1.

This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

See `?laqsp` auxiliary function that uses scaling factors computed by `?ppequ`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is packed in the array <code>ap</code> : If <code>uplo = 'U'</code> , the array <code>ap</code> stores the upper triangular part of the matrix A . If <code>uplo = 'L'</code> , the array <code>ap</code> stores the lower triangular part of the matrix A .
<code>n</code>	INTEGER. The order of matrix A ; $n \geq 0$.
<code>ap</code>	REAL for <code>spequ</code> DOUBLE PRECISION for <code>dpequ</code> COMPLEX for <code>cppequ</code> DOUBLE COMPLEX for <code>zppequ</code> .

Array, DIMENSION at least $\max(1, n(n+1)/2)$. The array *ap* contains the upper or the lower triangular part of the matrix *A* (as specified by *uplo*) in *packed storage* (see [Matrix Storage Schemes](#)).

Output Parameters

<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). If <i>info</i> = 0, the array <i>s</i> contains the scale factors for <i>A</i> .
<i>scond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>info</i> = 0, <i>scond</i> contains the ratio of the smallest <i>s</i> (<i>i</i>) to the largest <i>s</i> (<i>i</i>).
<i>amax</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Absolute value of the largest element of the matrix <i>A</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the <i>i</i> -th diagonal element of <i>A</i> is nonpositive.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ppequ` interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>s</i>	Holds the vector of length <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If *scond* ≥ 0.1 and *amax* is neither too large nor too small, it is not worth scaling by *s*.

If *amax* is very close to overflow or very close to underflow, the matrix *A* should be scaled.

?pbequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive-definite band matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call spbequ( uplo, n, kd, ab, ldab, s, scond, amax, info )
call dpbequ( uplo, n, kd, ab, ldab, s, scond, amax, info )
call cpbequ( uplo, n, kd, ab, ldab, s, scond, amax, info )
call zpbequ( uplo, n, kd, ab, ldab, s, scond, amax, info )
```

Fortran 95:

```
call pbequ( ab, s [,scond] [,amax] [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes row and column scalings intended to equilibrate a symmetric (Hermitian) positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). The output array s returns scale factors computed as

$$s(i) = \frac{1}{\sqrt{a_{i,i}}}$$

These factors are chosen so that the scaled matrix B with elements $b_{ij}=s(i)*a_{ij}*s(j)$ has diagonal elements equal to 1. This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

See [?laqsb](#) auxiliary function that uses scaling factors computed by `?pbequ`.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of <i>A</i> is packed in the array <i>ab</i> : If <i>uplo</i> = 'U', the array <i>ab</i> stores the upper triangular part of the matrix <i>A</i> . If <i>uplo</i> = 'L', the array <i>ab</i> stores the lower triangular part of the matrix <i>A</i> .
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>kd</i>	INTEGER. The number of superdiagonals or subdiagonals in the matrix <i>A</i> ; $kd \geq 0$.
<i>ab</i>	REAL for <i>spbequ</i> DOUBLE PRECISION for <i>dpbequ</i> COMPLEX for <i>cpbequ</i> DOUBLE COMPLEX for <i>zpbegu</i> . Array, DIMENSION (<i>ldab</i> , *). The array <i>ap</i> contains either the upper or the lower triangular part of the matrix <i>A</i> (as specified by <i>uplo</i>) in <i>band storage</i> (see Matrix Storage Schemes). The second dimension of <i>ab</i> must be at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The leading dimension of the array <i>ab</i> ; $ldab \geq kd + 1$.

Output Parameters

<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). If <i>info</i> = 0, the array <i>s</i> contains the scale factors for <i>A</i> .
<i>scond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>info</i> = 0, <i>scond</i> contains the ratio of the smallest $s(i)$ to the largest $s(i)$.
<i>amax</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Absolute value of the largest element of the matrix <i>A</i> .
<i>info</i>	INTEGER.

If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.
If *info* = *i*, the *i*-th diagonal element of *A* is nonpositive.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbequ` interface are as follows:

<i>ab</i>	Holds the array <i>A</i> of size $(kd+1, n)$.
<i>s</i>	Holds the vector of length <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

If *scond* ≥ 0.1 and *amax* is neither too large nor too small, it is not worth scaling by *s*.

If *amax* is very close to overflow or very close to underflow, the matrix *A* should be scaled.

?syequb

Computes row and column scaling factors intended to equilibrate a symmetric indefinite matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call ssyequb( uplo, n, a, lda, s, scnd, amax, work, info )
call dsyequb( uplo, n, a, lda, s, scnd, amax, work, info )
call csyequb( uplo, n, a, lda, s, scnd, amax, work, info )
call zsyequb( uplo, n, a, lda, s, scnd, amax, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes row and column scalings intended to equilibrate a symmetric indefinite matrix A and reduce its condition number (with respect to the two-norm).

The array s contains the scale factors, $s(i) = 1/\sqrt{A(i,i)}$. These factors are chosen so that the scaled matrix B with elements $b(i,j)=s(i)*a(i,j)*s(j)$ has ones on the diagonal.

This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of A is stored:
If *uplo* = 'U', the array a stores the upper triangular part of the matrix A .
If *uplo* = 'L', the array a stores the lower triangular part of the matrix A .

n INTEGER. The order of the matrix A ; $n \geq 0$.

a, work REAL for *ssyequb*
DOUBLE PRECISION for *dsyequb*
COMPLEX for *csyequb*
DOUBLE COMPLEX for *zsysequb*.
Array a : DIMENSION ($lda, *$).
Contains the n -by- n symmetric indefinite matrix A whose scaling factors are to be computed. Only the diagonal elements of A are referenced.
The second dimension of a must be at least $\max(1, n)$.
work()* is a workspace array. The dimension of *work* is at least $\max(1, 3*n)$.

lda INTEGER. The first dimension of a ; $lda \geq \max(1, m)$.

Output Parameters

s REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Array, DIMENSION (n).
If *info* = 0, the array s contains the scale factors for A .

scond REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.

If $info = 0$, $scond$ contains the ratio of the smallest $s(i)$ to the largest $s(i)$. If $scond \geq 0.1$, and $amax$ is neither too large nor too small, it is not worth scaling by s .

$amax$ REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Absolute value of the largest element of the matrix A . If $amax$ is very close to overflow or underflow, the matrix should be scaled.

$info$ INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.
If $info = i$, the i -th diagonal element of A is nonpositive.

?heequb

Computes row and column scaling factors intended to equilibrate a Hermitian indefinite matrix and reduce its condition number.

Syntax

FORTRAN 77:

```
call cheequb( uplo, n, a, lda, s, scnd, amax, work, info )
```

```
call zheequb( uplo, n, a, lda, s, scnd, amax, work, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine computes row and column scalings intended to equilibrate a Hermitian indefinite matrix A and reduce its condition number (with respect to the two-norm).

The array s contains the scale factors, $s(i) = 1/\sqrt{A(i,i)}$. These factors are chosen so that the scaled matrix B with elements $b(i,j) = s(i) * a(i,j) * s(j)$ has ones on the diagonal.

This choice of s puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

Input Parameters

$uplo$ CHARACTER*1. Must be 'U' or 'L'.

Indicates whether the upper or lower triangular part of A is stored:
 If $uplo = 'U'$, the array a stores the upper triangular part of the matrix A .
 If $uplo = 'L'$, the array a stores the lower triangular part of the matrix A .

n INTEGER. The order of the matrix A ; $n \geq 0$.

$a, work$ COMPLEX for cheequb
 DOUBLE COMPLEX for zheequb.
 Array a : DIMENSION ($lda, *$).
 Contains the n -by- n symmetric indefinite matrix A whose scaling factors are to be computed. Only the diagonal elements of A are referenced. The second dimension of a must be at least $\max(1, n)$.
 $work(*)$ is a workspace array. The dimension of $work$ is at least $\max(1, 3*n)$.

lda INTEGER. The first dimension of a ; $lda \geq \max(1, m)$.

Output Parameters

s REAL for cheequb
 DOUBLE PRECISION for zheequb.
 Array, DIMENSION (n).
 If $info = 0$, the array s contains the scale factors for A .

$scond$ REAL for cheequb
 DOUBLE PRECISION for zheequb.
 If $info = 0$, $scond$ contains the ratio of the smallest $s(i)$ to the largest $s(i)$. If $scond \geq 0.1$, and $amax$ is neither too large nor too small, it is not worth scaling by s .

$amax$ REAL for cheequb
 DOUBLE PRECISION for zheequb.
 Absolute value of the largest element of the matrix A . If $amax$ is very close to overflow or underflow, the matrix should be scaled.

$info$ INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info = i$, the i -th diagonal element of A is nonpositive.

Driver Routines

Table 3-3 lists the LAPACK driver routines for solving systems of linear equations with real or complex matrices.

Table 3-3 Driver Routines for Solving Systems of Linear Equations

complex symmetric, packed storage	<code>?spsv</code>	<code>?spsvx</code>	

In this table ? stands for s (single precision real), d (double precision real), c (single precision complex), or z (double precision complex). In the description of `?gesv` and `?posv` routines, the ? sign stands for combined character codes ds and zc for the mixed precision subroutines.

?gesv

Computes the solution to the system of linear equations with a square matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgesv( n, nrhs, a, lda, ipiv, b, ldb, info )
call dgesv( n, nrhs, a, lda, ipiv, b, ldb, info )
call cgesv( n, nrhs, a, lda, ipiv, b, ldb, info )
call zgesv( n, nrhs, a, lda, ipiv, b, ldb, info )
call dsgesv( n, nrhs, a, lda, ipiv, b, ldb, x, ldx, work, swork, iter, info )
call zcgesv( n, nrhs, a, lda, ipiv, b, ldb, x, ldx, work, swork, rwork, iter, info )
```

Fortran 95:

```
call gesv( a, b [,ipiv] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

<i>nrhs</i>	INTEGER. The number of right-hand sides, that is, the number of columns of the matrix B ; $nrhs \geq 0$.
<i>a, b</i>	REAL for <i>sgesv</i> DOUBLE PRECISION for <i>dgesv</i> and <i>dsgesv</i> COMPLEX for <i>cgesv</i> DOUBLE COMPLEX for <i>zgesv</i> and <i>zcgesv</i> . Arrays: $a(lda, *)$, $b(l db, *)$. The array a contains the n -by- n coefficient matrix A . The array b contains the n -by- $nrhs$ matrix of right hand side matrix B . The second dimension of a must be at least $\max(1, n)$, the second dimension of b at least $\max(1, nrhs)$.
<i>lda</i>	INTEGER. The leading dimension of the array a ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The leading dimension of the array b ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The leading dimension of the array x ; $ldx \geq \max(1, n)$.
<i>work</i>	DOUBLE PRECISION for <i>dsgesv</i> DOUBLE COMPLEX for <i>zcgesv</i> . Workspace array, DIMENSION at least $\max(1, n*nrhs)$. This array is used to hold the residual vectors.
<i>swork</i>	REAL for <i>dsgesv</i> COMPLEX for <i>zcgesv</i> . Workspace array, DIMENSION at least $\max(1, n*(n+nrhs))$. This array is used to use the single precision matrix and the right-hand sides or solutions in single precision.
<i>rwork</i>	DOUBLE PRECISION. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>a</i>	Overwritten by the factors L and U from the factorization of $A = P*L*U$; the unit diagonal elements of L are not stored. If iterative refinement has been successfully used ($info=0$ and $iter \geq 0$), then A is unchanged. If double precision factorization has been used ($info=0$ and $iter < 0$), then the array A contains the factors L and U from the factorization $A = P*L*U$; the unit diagonal elements of L are not stored.
<i>b</i>	Overwritten by the solution matrix X for <i>dgesv</i> , <i>sgesv</i> , <i>zgesv</i> , <i>zcgesv</i> . Unchanged for <i>dsgesv</i> and <i>zcgesv</i> .

<i>ipiv</i>	<p>INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row $ipiv(i)$. Corresponds to the single precision factorization (if $info=0$ and $iter \geq 0$) or the double precision factorization (if $info=0$ and $iter < 0$).</p>
<i>x</i>	<p>DOUBLE PRECISION for <code>dsgesv</code> DOUBLE COMPLEX for <code>zcgsv</code>. Array, DIMENSION ($ldx, nrhs$). If $info = 0$, contains the n-by-$nrhs$ solution matrix X.</p>
<i>iter</i>	<p>INTEGER. If $iter < 0$: iterative refinement has failed, double precision factorization has been performed</p> <ul style="list-style-type: none"> • If $iter = -1$: the routine fell back to full precision for implementation- or machine-specific reason • If $iter = -2$: narrowing the precision induced an overflow, the routine fell back to full precision • If $iter = -3$: failure of <code>sgetrf</code> for <code>dsgesv</code>, or <code>cgetrf</code> for <code>zcgsv</code> • If $iter = -31$: stop the iterative refinement after the 30th iteration. <p>If $iter > 0$: iterative refinement has been successfully used. Returns the number of iterations.</p>
<i>info</i>	<p>INTEGER. If $info=0$, the execution is successful. If $info = -i$, the i-th parameter had an illegal value. If $info = i, U(i, i)$ (computed in double precision for mixed precision subroutines) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gesv` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.

ipiv Holds the vector of length *n*.

NOTE. Fortran 95 Interface is so far not available for the mixed precision subroutines *dsgesv/zcgsv*.

?gesvx

Computes the solution to the system of linear equations with a square matrix A and multiple right-hand sides, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sgesvx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b,
            ldb, x, ldx, rcond, ferr, berr, work, iwork, info )
```

```
call dgesvx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b,
            ldb, x, ldx, rcond, ferr, berr, work, iwork, info )
```

```
call cgesvx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b,
            ldb, x, ldx, rcond, ferr, berr, work, rwork, info )
```

```
call zgesvx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b,
            ldb, x, ldx, rcond, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call gesvx( a, b, x [,af] [,ipiv] [,fact] [,trans] [,equed] [,r] [,c] [,ferr]
            [,berr] [,rcond] [,rpvgrw] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine uses the LU factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is an n -by- n matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?gesvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors r and c are computed to equilibrate the system:

$$\text{trans} = \text{'N'}: \text{diag}(r) * A * \text{diag}(c) * \text{inv}(\text{diag}(c)) * X = \text{diag}(r) * B$$

$$\text{trans} = \text{'T'}: (\text{diag}(r) * A * \text{diag}(c))^T * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

$$\text{trans} = \text{'C'}: (\text{diag}(r) * A * \text{diag}(c))^H * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(r) * A * \text{diag}(c)$ and B by $\text{diag}(r) * B$ (if `trans='N'`) or $\text{diag}(c) * B$ (if `trans = 'T'` or `'C'`).

2. If `fact = 'N'` or `'E'`, the LU decomposition is used to factor the matrix A (after equilibration if `fact = 'E'`) as $A = P * L * U$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.
3. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n + 1` is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
4. The system of equations is solved for x using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix x is premultiplied by $\text{diag}(c)$ (if `trans = 'N'`) or $\text{diag}(r)$ (if `trans = 'T'` or `'C'`) so that it solves the original system before equilibration.

Input Parameters

`fact` CHARACTER*1. Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If $fact = 'F'$: on entry, af and $ipiv$ contain the factored form of A . If $equed$ is not $'N'$, the matrix A has been equilibrated with scaling factors given by r and c .
 a , af , and $ipiv$ are not modified.

If $fact = 'N'$, the matrix A will be copied to af and factored.

If $fact = 'E'$, the matrix A will be equilibrated if necessary, then copied to af and factored.

trans CHARACTER*1. Must be $'N'$, $'T'$, or $'C'$.
 Specifies the form of the system of equations:
 If $trans = 'N'$, the system has the form $A^*X = B$ (No transpose).
 If $trans = 'T'$, the system has the form $A^T * X = B$ (Transpose).
 If $trans = 'C'$, the system has the form $A^H * X = B$ (Transpose for real flavors, conjugate transpose for complex flavors).

n INTEGER. The number of linear equations; the order of the matrix A ;
 $n \geq 0$.

nrhs INTEGER. The number of right hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.

a,af,b,work REAL for sgesvx
 DOUBLE PRECISION for dgesvx
 COMPLEX for cgesvx
 DOUBLE COMPLEX for zgesvx.
 Arrays: $a(lda, *)$, $af(ldaf, *)$, $b ldb, *)$, $work(*)$.
 The array a contains the matrix A . If $fact = 'F'$ and $equed$ is not $'N'$, then A must have been equilibrated by the scaling factors in r and/or c . The second dimension of a must be at least $\max(1, n)$.
 The array af is an input argument if $fact = 'F'$. It contains the factored form of the matrix A , that is, the factors L and U from the factorization $A = P * L * U$ as computed by `?getrf`. If $equed$ is not $'N'$, then af is the factored form of the equilibrated matrix A . The second dimension of af must be at least $\max(1, n)$.
 The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

work()* is a workspace array. The dimension of *work* must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, n)$.

ldaf INTEGER. The first dimension of *af*; $ldaf \geq \max(1, n)$.

ldb INTEGER. The first dimension of *b*; $ldb \geq \max(1, n)$.

ipiv INTEGER.
 Array, DIMENSION at least $\max(1, n)$. The array *ipiv* is an input argument if *fact* = 'F'. It contains the pivot indices from the factorization $A = P*L*U$ as computed by [?getrf](#); row *i* of the matrix was interchanged with row *ipiv(i)*.

equed CHARACTER*1. Must be 'N', 'R', 'C', or 'B'.
equed is an input argument if *fact* = 'F'. It specifies the form of equilibration that was done:
 If *equed* = 'N', no equilibration was done (always true if *fact* = 'N').
 If *equed* = 'R', row equilibration was done, that is, *A* has been premultiplied by *diag(r)*.
 If *equed* = 'C', column equilibration was done, that is, *A* has been postmultiplied by *diag(c)*.
 If *equed* = 'B', both row and column equilibration was done, that is, *A* has been replaced by *diag(r)*A*diag(c)*.

r, c REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Arrays: *r(n), c(n)*. The array *r* contains the row scale factors for *A*, and the array *c* contains the column scale factors for *A*. These arrays are input arguments if *fact* = 'F' only; otherwise they are output arguments.
 If *equed* = 'R' or 'B', *A* is multiplied on the left by *diag(r)*; if *equed* = 'N' or 'C', *r* is not accessed.
 If *fact* = 'F' and *equed* = 'R' or 'B', each element of *r* must be positive.
 If *equed* = 'C' or 'B', *A* is multiplied on the right by *diag(c)*; if *equed* = 'N' or 'R', *c* is not accessed.
 If *fact* = 'F' and *equed* = 'C' or 'B', each element of *c* must be positive.

<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.
<i>rwork</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Workspace array, DIMENSION at least $\max(1, 2*n)$; used in complex flavors only.

Output Parameters

<i>x</i>	REAL for sgesvx DOUBLE PRECISION for dgesvx COMPLEX for cgesvx DOUBLE COMPLEX for zgesvx. Array, DIMENSION (<i>ldx</i> , *). If <i>info</i> = 0 or <i>info</i> = <i>n</i> +1, the array <i>x</i> contains the solution matrix <i>x</i> to the <i>original</i> system of equations. Note that <i>A</i> and <i>B</i> are modified on exit if <i>equed</i> \neq 'N', and the solution to the <i>equilibrated</i> system is: $diag(C)^{-1}*X$, if <i>trans</i> = 'N' and <i>equed</i> = 'C' or 'B'; $diag(R)^{-1}*X$, if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'R' or 'B'. The second dimension of <i>x</i> must be at least $\max(1, nrhs)$.
<i>a</i>	Array <i>a</i> is not modified on exit if <i>fact</i> = 'F' or 'N', or if <i>fact</i> = 'E' and <i>equed</i> = 'N'. If <i>equed</i> \neq 'N', <i>A</i> is scaled on exit as follows: <i>equed</i> = 'R': $A = diag(R)*A$ <i>equed</i> = 'C': $A = A*diag(c)$ <i>equed</i> = 'B': $A = diag(R)*A*diag(c)$.
<i>af</i>	If <i>fact</i> = 'N' or 'E', then <i>af</i> is an output argument and on exit returns the factors <i>L</i> and <i>U</i> from the factorization $A = PLU$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E'). See the description of <i>a</i> for the form of the equilibrated matrix.
<i>b</i>	Overwritten by $diag(r)*B$ if <i>trans</i> = 'N' and <i>equed</i> = 'R' or 'B'; overwritten by $diag(c)*B$ if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'C' or 'B'; not changed if <i>equed</i> = 'N'.

<i>r, c</i>	These arrays are output arguments if <i>fact</i> ≠ 'F'. See the description of <i>r, c</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.
<i>ferr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector <i>x</i> (<i>j</i>) (the <i>j</i> -th column of the solution matrix <i>X</i>). If <i>xtrue</i> is the true solution corresponding to <i>x</i> (<i>j</i>), <i>ferr</i> (<i>j</i>) is an estimated upper bound for the magnitude of the largest element in (<i>x</i> (<i>j</i>) - <i>xtrue</i>) divided by the magnitude of the largest element in <i>x</i> (<i>j</i>). The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector <i>x</i> (<i>j</i>), that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes <i>x</i> (<i>j</i>) an exact solution.
<i>ipiv</i>	If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E').
<i>equed</i>	If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>work, rwork</i>	On exit, <i>work</i> (1) for real flavors, or <i>rwork</i> (1) for complex flavors, contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If <i>work</i> (1) for real flavors, or <i>rwork</i> (1) for complex flavors is much less than 1, then the stability of the <i>LU</i> factorization of the (equilibrated) matrix <i>A</i> could be poor. This also means that the solution <i>x</i> , condition estimator <i>rcond</i> , and forward error bound <i>ferr</i> could be unreliable. If factorization fails with $0 <$

$info \leq n$, then $work(1)$ for real flavors, or $rwork(1)$ for complex flavors contains the reciprocal pivot growth factor for the leading $info$ columns of A .

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and $i \leq n$, then $U(i, i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n+1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gesvx` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>af</i>	Holds the matrix AF of size (n, n) .
<i>ipiv</i>	Holds the vector of length n .
<i>r</i>	Holds the vector of length n . Default value for each element is $r(i) = 1.0_WP$.
<i>c</i>	Holds the vector of length n . Default value for each element is $c(i) = 1.0_WP$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>fact</i>	Must be 'N', 'E', or 'F'. The default value is 'N'. If $fact = 'F'$, then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.

<i>equed</i>	Must be 'N', 'B', 'C', or 'R'. The default value is 'N'.
<i>rpvgrw</i>	Real value that contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$.

?gesvxx

Uses extra precise iterative refinement to compute the solution to the system of linear equations with a square matrix A and multiple right-hand sides

Syntax

FORTRAN 77:

```
call sgesvxx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b,  
ldb, x, ldx, rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp,  
nparams, params, work, iwork, info )
```

```
call dgesvxx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b,  
ldb, x, ldx, rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp,  
nparams, params, work, iwork, info )
```

```
call cgesvxx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b,  
ldb, x, ldx, rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp,  
nparams, params, work, rwork, info )
```

```
call zgesvxx( fact, trans, n, nrhs, a, lda, af, ldaf, ipiv, equed, r, c, b,  
ldb, x, ldx, rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp,  
nparams, params, work, rwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine uses the LU factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is an n -by- n matrix, the columns of the matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine `?gesvxx` performs the following steps:

1. If *fact* = 'E', scaling factors *r* and *c* are computed to equilibrate the system:

$$\text{trans} = \text{'N'}: \text{diag}(r) * A * \text{diag}(c) * \text{inv}(\text{diag}(c)) * X = \text{diag}(r) * B$$

$$\text{trans} = \text{'T'}: (\text{diag}(r) * A * \text{diag}(c))^T * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

$$\text{trans} = \text{'C'}: (\text{diag}(r) * A * \text{diag}(c))^H * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix *A*, but if equilibration is used, *A* is overwritten by $\text{diag}(r) * A * \text{diag}(c)$ and *B* by $\text{diag}(r) * B$ (if *trans*='N') or $\text{diag}(c) * B$ (if *trans* = 'T' or 'C').

2. If *fact* = 'N' or 'E', the LU decomposition is used to factor the matrix *A* (after equilibration if *fact* = 'E') as $A = P * L * U$, where *P* is a permutation matrix, *L* is a unit lower triangular matrix, and *U* is upper triangular.
3. If some $U_{i,i} = 0$, so that *U* is exactly singular, then the routine returns with *info* = *i*. Otherwise, the factored form of *A* is used to estimate the condition number of the matrix *A* (see the *rcond* parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for *x* and compute error bounds.
4. The system of equations is solved for *x* using the factored form of *A*.
5. By default, unless `params(la_linrx_itref_i)` is set to zero, the routine applies iterative refinement to improve the computed solution matrix and calculate error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix *x* is premultiplied by $\text{diag}(c)$ (if *trans* = 'N') or $\text{diag}(r)$ (if *trans* = 'T' or 'C') so that it solves the original system before equilibration.

Input Parameters

fact CHARACTER*1. Must be 'F', 'N', or 'E'.
Specifies whether or not the factored form of the matrix *A* is supplied on entry, and if not, whether the matrix *A* should be equilibrated before it is factored.

If *fact* = 'F', on entry, *af* and *ipiv* contain the factored form of *A*. If *equed* is not 'N', the matrix *A* has been equilibrated with scaling factors given by *r* and *c*. Parameters *a*, *af*, and *ipiv* are not modified. If *fact* = 'N', the matrix *A* will be copied to *af* and factored. If *fact* = 'E', the matrix *A* will be equilibrated, if necessary, copied to *af* and factored.

trans CHARACTER*1. Must be 'N', 'T', or 'C'. Specifies the form of the system of equations: If *trans* = 'N', the system has the form $A * X = B$ (No transpose). If *trans* = 'T', the system has the form $A^{**T} * X = B$ (Transpose). If *trans* = 'C', the system has the form $A^{**H} * X = B$ (Conjugate Transpose = Transpose for real flavors, Conjugate Transpose for complex flavors).

n INTEGER. The number of linear equations; the order of the matrix *A*; $n \geq 0$.

nrhs INTEGER. The number of right hand sides; the number of columns of the matrices *B* and *X*; $nrhs \geq 0$.

a, *af*, *b*, *work* REAL for sgesvxx
DOUBLE PRECISION for dgesvxx
COMPLEX for cgesvxx
DOUBLE COMPLEX for zgesvxx.
Arrays: *a*(*lda*,*), *af*(*ldaf*,*), *b*(*ldb*,*), *work*(*). The array *a* contains the matrix *A*. If *fact* = 'F' and *equed* is not 'N', then *A* must have been equilibrated by the scaling factors in *r* and/or *c*. The second dimension of *a* must be at least $\max(1, n)$. The array *af* is an input argument if *fact* = 'F'. It contains the factored form of the matrix *A*, that is, the factors *L* and *U* from the factorization $A = P * L * U$ as computed by ?getrf. If *equed* is not 'N', then *af* is the factored form of the equilibrated matrix *A*. The second dimension of *af* must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.
 $work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

lda INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.

ldaf INTEGER. The first dimension of af ; $ldaf \geq \max(1, n)$.

ipiv INTEGER.
 Array, DIMENSION at least $\max(1, n)$. The array $ipiv$ is an input argument if $fact = 'F'$. It contains the pivot indices from the factorization $A = P*L*U$ as computed by `?getrf`; row i of the matrix was interchanged with row $ipiv(i)$.

equed CHARACTER*1. Must be 'N', 'R', 'C', or 'B'.
 $equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:
 If $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$).
 If $equed = 'R'$, row equilibration was done, that is, A has been premultiplied by $diag(r)$.
 If $equed = 'C'$, column equilibration was done, that is, A has been postmultiplied by $diag(c)$.
 If $equed = 'B'$, both row and column equilibration was done, that is, A has been replaced by $diag(r)*A*diag(c)$.

r, c REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Arrays: $r(n), c(n)$. The array r contains the row scale factors for A , and the array c contains the column scale factors for A . These arrays are input arguments if $fact = 'F'$ only; otherwise they are output arguments.
 If $equed = 'R'$ or 'B', A is multiplied on the left by $diag(r)$; if $equed = 'N'$ or 'C', r is not accessed.
 If $fact = 'F'$ and $equed = 'R'$ or 'B', each element of r must be positive.
 If $equed = 'C'$ or 'B', A is multiplied on the right by $diag(c)$; if $equed = 'N'$ or 'R', c is not accessed.

If *fact* = 'F' and *equed* = 'C' or 'B', each element of *c* must be positive.

Each element of *x* or *c* should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

<i>ldb</i>	INTEGER. The first dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>n_err_bnds</i>	INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in <i>Output Arguments</i> section below.
<i>nparams</i>	INTEGER. Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used.
<i>params</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION <i>nparams</i> . Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <i>nparams</i> = 0, which prevents the source code from accessing the <i>params</i> argument. <i>params</i> (<i>la_linrx_itref_i</i> = 1) : Whether to perform iterative refinement or not. Default: 1.0 =0.0 No refinement is performed and no error bounds are computed.

=1.0 Use the double-precision refinement algorithm, possibly with doubled-single computations if the compilation environment does not support `DOUBLE PRECISION`.

(Other values are reserved for future use.)

`params(la_linrx_ithresh_i = 2)` : Maximum number of residual computations allowed for refinement.

Default 10

Aggressive Set to 100 to permit convergence using approximate factorizations or factorizations other than *LU*. If the factorization uses a technique other than Gaussian elimination, the guarantees in `err_bnds_norm` and `err_bnds_comp` may no longer be trustworthy.

`params(la_linrx_cwise_i = 3)` : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

`iwork` INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

`rwork` REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.

Output Parameters

`x` REAL for `sgesvxx`
 DOUBLE PRECISION for `dgesvxx`
 COMPLEX for `cgesvxx`
 DOUBLE COMPLEX for `zgesvxx`.
 Array, DIMENSION (`ldx`, *).

If $info = 0$, the array x contains the solution n -by- $nrhs$ matrix x to the *original* system of equations. Note that A and B are modified on exit if $equed \neq 'N'$, and the solution to the *equilibrated* system is:
 $inv(diag(c)) * X$, if $trans = 'N'$ and $equed = 'C'$ or $'B'$; or $inv(diag(r)) * X$, if $trans = 'T'$ or $'C'$ and $equed = 'R'$ or $'B'$. The second dimension of x must be at least $\max(1, nrhs)$.

a Array a is not modified on exit if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$.
 If $equed \neq 'N'$, A is scaled on exit as follows:
 $equed = 'R'$: $A = diag(r) * A$
 $equed = 'C'$: $A = A * diag(c)$
 $equed = 'B'$: $A = diag(r) * A * diag(c)$.

af If $fact = 'N'$ or $'E'$, then af is an output argument and on exit returns the factors L and U from the factorization $A = PLU$ of the original matrix A (if $fact = 'N'$) or of the equilibrated matrix A (if $fact = 'E'$). See the description of a for the form of the equilibrated matrix.

b Overwritten by $diag(r) * B$ if $trans = 'N'$ and $equed = 'R'$ or $'B'$;
 overwritten by $trans = 'T'$ or $'C'$ and $equed = 'C'$ or $'B'$;
 not changed if $equed = 'N'$.

r, c These arrays are output arguments if $fact \neq 'F'$. Each element of these arrays is a power of the radix. See the description of r, c in *Input Arguments* section.

$rcond$ REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

<i>rpvgrw</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Contains the reciprocal pivot growth factor $norm(A) / norm(U)$. The <i>max absolute element</i> norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix <i>A</i> could be poor. This also means that the solution <i>x</i>, estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < info \leq n$, this parameter contains the reciprocal pivot growth factor for the leading <i>info</i> columns of <i>A</i>. In ?gesvx, this quantity is returned in <i>work(1)</i>.</p>
<i>berr</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes $x(j)$ an exact solution.</p>
<i>err_bnds_norm</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>nrhs</i>, <i>n_err_bnds</i>). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows: Normwise relative error in the <i>i</i>-th solution vector</p> $\frac{\max_j X_{true_{ji}} - X_{ji} }{\max_j X_{ji} }$ <p>The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned. The first index in <i>err_bnds_norm(i, :)</i> corresponds to the <i>i</i>-th right-hand side. The second index in <i>err_bnds_norm(, err)</i> contains the following three fields:</p>

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z . Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

err_bnds_comp

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:
 Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested ($params(3) = 0.0$), then `err_bnds_comp` is not accessed. If $n_err_bnds < 3$, then at most the first $(: , n_err_bnds)$ entries are returned.

The first index in `err_bnds_comp(i, :)` corresponds to the i -th right-hand side.

The second index in `err_bnds_comp(:, err)` contains the following three fields:

- `err=1` "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.
- `err=2` "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
- `err=3` Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error

estimate is "guaranteed". These reciprocal condition numbers are $1/(\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z . Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

ipiv If *fact* = 'N' or 'E', then *ipiv* is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the original matrix A (if *fact* = 'N') or of the equilibrated matrix A (if *fact* = 'E').

equed If *fact* ≠ 'F', then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

info INTEGER. If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed. If *info* = -*i*, the *i*-th parameter had an illegal value. If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned. If *info* = $n + j$: The solution corresponding to the *j*-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides *k* with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested *params*(3) = 0.0, then the *j*-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest *j* such that $\text{err_bnds_norm}(j, 1) = 0.0$ or $\text{err_bnds_comp}(j, 1) = 0.0$. See the definition of $\text{err_bnds_norm}(\cdot, 1)$ and $\text{err_bnds_comp}(\cdot, 1)$). To get information about all of the right-hand sides, check *err_bnds_norm* or *err_bnds_comp*.

?gbsv

Computes the solution to the system of linear equations with a band matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgbsv( n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call dgbsv( n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call cgbsv( n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
call zgbsv( n, kl, ku, nrhs, ab, ldab, ipiv, b, ldb, info )
```

Fortran 95:

```
call gbsv( ab, b [,kl] [,ipiv] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the real or complex system of linear equations $A * X = B$, where A is an n -by- n band matrix with kl subdiagonals and ku superdiagonals, the columns of matrix B are individual right-hand sides, and the columns of x are the corresponding solutions.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = L * U$, where L is a product of permutation and unit lower triangular matrices with kl subdiagonals, and U is upper triangular with $kl + ku$ superdiagonals. The factored form of A is then used to solve the system of equations $A * X = B$.

Input Parameters

<i>n</i>	INTEGER. The order of A . The number of rows in B ; $n \geq 0$.
<i>kl</i>	INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.
<i>ku</i>	INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides. The number of columns in B ; $nrhs \geq 0$.

<i>ab, b</i>	<p>REAL for <i>sghsv</i> DOUBLE PRECISION for <i>dghsv</i> COMPLEX for <i>cghsv</i> DOUBLE COMPLEX for <i>zghsv</i>. Arrays: <i>ab(ldab,*)</i>, <i>b(ldb,*)</i>. The array <i>ab</i> contains the matrix <i>A</i> in band storage (see Matrix Storage Schemes). The second dimension of <i>ab</i> must be at least $\max(1, n)$. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.</p>
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> . ($ldab \geq 2kl + ku + 1$)
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>ab</i>	Overwritten by <i>L</i> and <i>U</i> . The diagonal and $kl + ku$ superdiagonals of <i>U</i> are stored in the first $1 + kl + ku$ rows of <i>ab</i> . The multipliers used to form <i>L</i> are stored in the next <i>kl</i> rows.
<i>b</i>	Overwritten by the solution matrix <i>x</i> .
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The pivot indices: row <i>i</i> was interchanged with row <i>ipiv(i)</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , <i>U</i> (<i>i, i</i>) is exactly zero. The factorization has been completed, but the factor <i>U</i> is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ghsv* interface are as follows:

<i>ab</i>	Holds the array <i>A</i> of size $(2*kl+ku+1, n)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length <i>n</i> .

<i>kl</i>	If omitted, assumed $kl = ku$.
<i>ku</i>	Restored as $ku = lda - 2 * kl - 1$.

?gbsvx

Computes the solution to the real or complex system of linear equations with a band matrix A and multiple right-hand sides, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sgbsvx( fact, trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, equed,
r, c, b, ldb, x, ldx, rcond, ferr, berr, work, iwork, info )
call dgbsvx( fact, trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, equed,
r, c, b, ldb, x, ldx, rcond, ferr, berr, work, iwork, info )
call cgbsvx( fact, trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, equed,
r, c, b, ldb, x, ldx, rcond, ferr, berr, work, rwork, info )
call zgbsvx( fact, trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, equed,
r, c, b, ldb, x, ldx, rcond, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call gbsvx( ab, b, x [,kl] [,afb] [,ipiv] [,fact] [,trans] [,equed] [,r] [,c]
[,ferr] [,berr] [,rcond] [,rpvgrw] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine uses the LU factorization to compute the solution to a real or complex system of linear equations $A * X = B$, $A^T * X = B$, or $A^H * X = B$, where A is a band matrix of order n with kl subdiagonals and ku superdiagonals, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?gbsvx performs the following steps:

1. If $fact = 'E'$, real scaling factors r and c are computed to equilibrate the system:

$$trans = 'N': diag(r)*A*diag(c) *inv(diag(c))*X = diag(r)*B$$

$$trans = 'T': (diag(r)*A*diag(c))^T *inv(diag(r))*X = diag(c)*B$$

$$trans = 'C': (diag(r)*A*diag(c))^H *inv(diag(r))*X = diag(c)*B$$

Whether the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(r)*A*diag(c)$ and B by $diag(r)*B$ (if $trans='N'$) or $diag(c)*B$ (if $trans = 'T'$ or $'C'$).

2. If $fact = 'N'$ or $'E'$, the LU decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as $A = L*U$, where L is a product of permutation and unit lower triangular matrices with kl subdiagonals, and U is upper triangular with $kl+ku$ superdiagonals.
3. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n + 1$ is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
4. The system of equations is solved for x using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix x is premultiplied by $diag(c)$ (if $trans = 'N'$) or $diag(r)$ (if $trans = 'T'$ or $'C'$) so that it solves the original system before equilibration.

Input Parameters

fact CHARACTER*1. Must be 'F', 'N', or 'E'.
 Specifies whether the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.
 If $fact = 'F'$: on entry, *afb* and *ipiv* contain the factored form of A . If *equed* is not 'N', the matrix A is equilibrated with scaling factors given by r and c .
ab, *afb*, and *ipiv* are not modified.
 If $fact = 'N'$, the matrix A will be copied to *afb* and factored.
 If $fact = 'E'$, the matrix A will be equilibrated if necessary, then copied to *afb* and factored.

trans CHARACTER*1. Must be 'N', 'T', or 'C'.

Specifies the form of the system of equations:
 If *trans* = 'N', the system has the form $A^*X = B$ (No transpose).
 If *trans* = 'T', the system has the form $A^T * X = B$ (Transpose).
 If *trans* = 'C', the system has the form $A^H * X = B$ (Transpose for real flavors, conjugate transpose for complex flavors).

n INTEGER. The number of linear equations, the order of the matrix *A*; $n \geq 0$.

kl INTEGER. The number of subdiagonals within the band of *A*; $kl \geq 0$.

ku INTEGER. The number of superdiagonals within the band of *A*; $ku \geq 0$.

nrhs INTEGER. The number of right hand sides, the number of columns of the matrices *B* and *X*; $nrhs \geq 0$.

ab, afb, b, work REAL for sgesvx
 DOUBLE PRECISION for dgesvx
 COMPLEX for cgesvx
 DOUBLE COMPLEX for zgesvx.
 Arrays: *a(lda,*)*, *af(ldaf,*)*, *b ldb,*)*, *work(*)*.
 The array *ab* contains the matrix *A* in band storage (see [Matrix Storage Schemes](#)). The second dimension of *ab* must be at least $\max(1, n)$.
 If *fact* = 'F' and *equed* is not 'N', then *A* must have been equilibrated by the scaling factors in *r* and/or *c*.
 The array *afb* is an input argument if *fact* = 'F'. The second dimension of *afb* must be at least $\max(1, n)$. It contains the factored form of the matrix *A*, that is, the factors *L* and *U* from the factorization $A = L * U$ as computed by [?gbtrf](#). *U* is stored as an upper triangular band matrix with $kl + ku$ superdiagonals in the first $1 + kl + ku$ rows of *afb*. The multipliers used during the factorization are stored in the next *kl* rows. If *equed* is not 'N', then *afb* is the factored form of the equilibrated matrix *A*.
 The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations. The second dimension of *b* must be at least $\max(1, nrhs)$.
work()* is a workspace array. The dimension of *work* must be at least $\max(1, 3 * n)$ for real flavors, and at least $\max(1, 2 * n)$ for complex flavors.

ldab INTEGER. The first dimension of *ab*; $ldab \geq kl + ku + 1$.

ldafb INTEGER. The first dimension of *afb*; $ldafb \geq 2 * kl + ku + 1$.

<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains the pivot indices from the factorization $A = L*U$ as computed by ?gbtrf; row <i>i</i> of the matrix was interchanged with row <i>ipiv</i> (<i>i</i>).
<i>equed</i>	CHARACTER*1. Must be 'N', 'R', 'C', or 'B'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N'). If <i>equed</i> = 'R', row equilibration was done, that is, <i>A</i> has been premultiplied by <i>diag</i> (<i>r</i>). If <i>equed</i> = 'C', column equilibration was done, that is, <i>A</i> has been postmultiplied by <i>diag</i> (<i>c</i>). if <i>equed</i> = 'B', both row and column equilibration was done, that is, <i>A</i> has been replaced by <i>diag</i> (<i>r</i>)* <i>A</i> * <i>diag</i> (<i>c</i>).
<i>r, c</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: <i>r</i> (<i>n</i>), <i>c</i> (<i>n</i>). The array <i>r</i> contains the row scale factors for <i>A</i> , and the array <i>c</i> contains the column scale factors for <i>A</i> . These arrays are input arguments if <i>fact</i> = 'F' only; otherwise they are output arguments. If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by <i>diag</i> (<i>r</i>); if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive. If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by <i>diag</i> (<i>c</i>); if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'C' or 'B', each element of <i>c</i> must be positive.
<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.
<i>rwork</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

<i>x</i>	<p>REAL for <i>sgbsvx</i> DOUBLE PRECISION for <i>dgbsvx</i> COMPLEX for <i>cgbsvx</i> DOUBLE COMPLEX for <i>zgbsvx</i>. Array, DIMENSION (<i>ldx</i>, *). If <i>info</i> = 0 or <i>info</i> = <i>n</i>+1, the array <i>x</i> contains the solution matrix <i>x</i> to the <i>original</i> system of equations. Note that <i>A</i> and <i>B</i> are modified on exit if <i>equed</i> ≠ 'N', and the solution to the <i>equilibrated</i> system is: $\text{inv}(\text{diag}(c)) * X$, if <i>trans</i> = 'N' and <i>equed</i> = 'C' or 'B'; $\text{inv}(\text{diag}(r)) * X$, if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'R' or 'B'. The second dimension of <i>x</i> must be at least $\max(1, nrhs)$.</p>
<i>ab</i>	<p>Array <i>ab</i> is not modified on exit if <i>fact</i> = 'F' or 'N', or if <i>fact</i> = 'E' and <i>equed</i> = 'N'. If <i>equed</i> ≠ 'N', <i>A</i> is scaled on exit as follows: <i>equed</i> = 'R': $A = \text{diag}(r) * A$ <i>equed</i> = 'C': $A = A * \text{diag}(c)$ <i>equed</i> = 'B': $A = \text{diag}(r) * A * \text{diag}(c)$.</p>
<i>afb</i>	<p>If <i>fact</i> = 'N' or 'E', then <i>afb</i> is an output argument and on exit returns details of the <i>LU</i> factorization of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E'). See the description of <i>ab</i> for the form of the equilibrated matrix.</p>
<i>b</i>	<p>Overwritten by $\text{diag}(r) * b$ if <i>trans</i> = 'N' and <i>equed</i> = 'R' or 'B'; overwritten by $\text{diag}(c) * b$ if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'C' or 'B'; not changed if <i>equed</i> = 'N'.</p>
<i>r, c</i>	<p>These arrays are output arguments if <i>fact</i> ≠ 'F'. See the description of <i>r, c</i> in <i>Input Arguments</i> section.</p>
<i>rcond</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done).</p>

	<p>If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.</p>
<i>ferr</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j-th column of the solution matrix x). If x_{true} is the true solution corresponding to $x(j)$, $ferr(j)$ is an estimated upper bound for the magnitude of the largest element in $(x(j) - x_{true})$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for <i>rcond</i>, and is almost always a slight overestimate of the true error.</p>
<i>berr</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.</p>
<i>ipiv</i>	<p>If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the original matrix A (if <i>fact</i> = 'N') or of the equilibrated matrix A (if <i>fact</i> = 'E').</p>
<i>equed</i>	<p>If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).</p>
<i>work, rwork</i>	<p>On exit, <i>work</i>(1) for real flavors, or <i>rwork</i>(1) for complex flavors, contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If <i>work</i>(1) for real flavors, or <i>rwork</i>(1) for complex flavors is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution x, condition estimator <i>rcond</i>, and forward error bound <i>ferr</i> could be unreliable. If factorization fails with $0 < info \leq n$, then <i>work</i>(1) for real flavors, or <i>rwork</i>(1) for complex flavors contains the reciprocal pivot growth factor for the leading <i>info</i> columns of A.</p>
<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

If $info = i$, and $i \leq n$, then $U(i, i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned. If $info = i$, and $i = n+1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gbsvx` interface are as follows:

<code>ab</code>	Holds the array A of size $(kl+ku+1, n)$.
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>x</code>	Holds the matrix X of size $(n, nrhs)$.
<code>afb</code>	Holds the array AF of size $(2*kl+ku+1, n)$.
<code>ipiv</code>	Holds the vector of length n .
<code>r</code>	Holds the vector of length n . Default value for each element is $r(i) = 1.0_WP$.
<code>c</code>	Holds the vector of length n . Default value for each element is $c(i) = 1.0_WP$.
<code>ferr</code>	Holds the vector of length $(nrhs)$.
<code>berr</code>	Holds the vector of length $(nrhs)$.
<code>trans</code>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<code>equed</code>	Must be 'N', 'B', 'C', or 'R'. The default value is 'N'.
<code>fact</code>	Must be 'N', 'E', or 'F'. The default value is 'N'. If <code>fact = 'F'</code> , then both arguments <code>af</code> and <code>ipiv</code> must be present; otherwise, an error is returned.
<code>rpvgrw</code>	Real value that contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$.
<code>kl</code>	If omitted, assumed $kl = ku$.
<code>ku</code>	Restored as $ku = lda-kl-1$.

?gbsvxx

Uses extra precise iterative refinement to compute the solution to the system of linear equations with a banded matrix A and multiple right-hand sides

Syntax

FORTRAN 77:

```
call sgbsvxx( fact, trans, n, kl, ku, nrhs, ab, ldab, afb, ldafb, ipiv, equed,

err_bnds_comp, nparams, params, work, rwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine uses the LU factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is an n -by- n banded matrix, the columns of the matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine `?gbsvxx` performs the following steps:

1. If *fact* = 'E', scaling factors *r* and *c* are computed to equilibrate the system:

$$\text{trans} = \text{'N'}: \text{diag}(r) * A * \text{diag}(c) * \text{inv}(\text{diag}(c)) * X = \text{diag}(r) * B$$

$$\text{trans} = \text{'T'}: (\text{diag}(r) * A * \text{diag}(c))^T * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

$$\text{trans} = \text{'C'}: (\text{diag}(r) * A * \text{diag}(c))^H * \text{inv}(\text{diag}(r)) * X = \text{diag}(c) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix *A*, but if equilibration is used, *A* is overwritten by $\text{diag}(r) * A * \text{diag}(c)$ and *B* by $\text{diag}(r) * B$ (if *trans*='N') or $\text{diag}(c) * B$ (if *trans* = 'T' or 'C').

2. If *fact* = 'N' or 'E', the LU decomposition is used to factor the matrix *A* (after equilibration if *fact* = 'E') as $A = P * L * U$, where *P* is a permutation matrix, *L* is a unit lower triangular matrix, and *U* is upper triangular.
3. If some $U_{i,i} = 0$, so that *U* is exactly singular, then the routine returns with *info* = *i*. Otherwise, the factored form of *A* is used to estimate the condition number of the matrix *A* (see the *rcond* parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for *x* and compute error bounds.
4. The system of equations is solved for *x* using the factored form of *A*.
5. By default, unless `params(la_linrx_itref_i)` is set to zero, the routine applies iterative refinement to improve the computed solution matrix and calculate error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix *x* is premultiplied by $\text{diag}(c)$ (if *trans* = 'N') or $\text{diag}(r)$ (if *trans* = 'T' or 'C') so that it solves the original system before equilibration.

Input Parameters

fact CHARACTER*1. Must be 'F', 'N', or 'E'.
Specifies whether or not the factored form of the matrix *A* is supplied on entry, and if not, whether the matrix *A* should be equilibrated before it is factored.

If $fact = 'F'$, on entry, afb and $ipiv$ contain the factored form of A . If $equed$ is not $'N'$, the matrix A has been equilibrated with scaling factors given by r and c . Parameters ab , afb , and $ipiv$ are not modified. If $fact = 'N'$, the matrix A will be copied to afb and factored. If $fact = 'E'$, the matrix A will be equilibrated, if necessary, copied to afb and factored.

trans CHARACTER*1. Must be $'N'$, $'T'$, or $'C'$. Specifies the form of the system of equations:
 If $trans = 'N'$, the system has the form $A*X = B$ (No transpose).
 If $trans = 'T'$, the system has the form $A^{**T}*X = B$ (Transpose).
 If $trans = 'C'$, the system has the form $A^{**H}*X = B$ (Conjugate Transpose = Transpose for real flavors, Conjugate Transpose for complex flavors).

n INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.

kl INTEGER. The number of subdiagonals within the band of A ; $kl \geq 0$.

ku INTEGER. The number of superdiagonals within the band of A ; $ku \geq 0$.

nrhs INTEGER. The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.

ab, afb, b, work REAL for `sgbsvxx`
 DOUBLE PRECISION for `dgbsvxx`
 COMPLEX for `cgbsvxx`
 DOUBLE COMPLEX for `zgbsvxx`.
 Arrays: $ab(ldab, *)$, $afb(ldafb, *)$, $b(l db, *)$, $work(*)$.
 The array ab contains the matrix A in band storage, in rows 1 to $kl+ku+1$. The j -th column of A is stored in the j -th column of the array ab as follows:
 $ab(ku+1+i-j, j) = A(i, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

If $fact = 'F'$ and $equed$ is not $'N'$, then AB must have been equilibrated by the scaling factors in r and/or c . The second dimension of a must be at least $\max(1, n)$.

The array afb is an input argument if $fact = 'F'$. It contains the factored form of the banded matrix A , that is, the factors L and U from the factorization $A = P*L*U$ as computed by `?gbtrf`. U is stored as an upper triangular banded matrix with $kl + ku$ superdiagonals in rows 1 to $kl + ku + 1$. The multipliers used during the factorization are stored in rows $kl + ku + 2$ to $2*kl + ku + 1$. If $equed$ is not $'N'$, then afb is the factored form of the equilibrated matrix A .

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

<i>ldab</i>	INTEGER. The first dimension of the array ab ; $ldab \geq kl+ku+1$.
<i>ldafb</i>	INTEGER. The first dimension of the array afb ; $ldafb \geq 2*kl+ku+1$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array $ipiv$ is an input argument if $fact = 'F'$. It contains the pivot indices from the factorization $A = P*L*U$ as computed by <code>?gbtrf</code> ; row i of the matrix was interchanged with row $ipiv(i)$.
<i>equed</i>	CHARACTER*1. Must be $'N'$, $'R'$, $'C'$, or $'B'$. $equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done: If $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$). If $equed = 'R'$, row equilibration was done, that is, A has been premultiplied by $diag(r)$. If $equed = 'C'$, column equilibration was done, that is, A has been postmultiplied by $diag(c)$.

<i>r, c</i>	<p>If <i>equed</i> = 'B', both row and column equilibration was done, that is, <i>A</i> has been replaced by $diag(r)*A*diag(c)$.</p> <p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors.</p> <p>Arrays: <i>r</i>(<i>n</i>), <i>c</i>(<i>n</i>). The array <i>r</i> contains the row scale factors for <i>A</i>, and the array <i>c</i> contains the column scale factors for <i>A</i>. These arrays are input arguments if <i>fact</i> = 'F' only; otherwise they are output arguments.</p> <p>If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by $diag(r)$; if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed.</p> <p>If <i>fact</i> = 'F' and <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive.</p> <p>If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by $diag(c)$; if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed.</p> <p>If <i>fact</i> = 'F' and <i>equed</i> = 'C' or 'B', each element of <i>c</i> must be positive.</p> <p>Each element of <i>r</i> or <i>c</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.</p>
<i>ldb</i>	<p>INTEGER. The first dimension of the array <i>b</i>; $ldb \geq \max(1, n)$.</p>
<i>ldx</i>	<p>INTEGER. The first dimension of the output array <i>x</i>; $ldx \geq \max(1, n)$.</p>
<i>n_err_bnds</i>	<p>INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in <i>Output Arguments</i> section below.</p>
<i>nparams</i>	<p>INTEGER. Specifies the number of parameters set in <i>params</i>. If ≤ 0, the <i>params</i> array is never referenced and default values are used.</p>
<i>params</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors.</p>

Array, DIMENSION *nparams*. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with default value used for that parameter. Only positions up to *nparams* are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass *nparams* = 0, which prevents the source code from accessing the *params* argument.

params(*la_linrx_itref_i* = 1) : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).

=0.0 No refinement is performed and no error bounds are computed.

=1.0 Use the extra-precise refinement algorithm.

(Other values are reserved for future use.)

params(*la_linrx_ithresh_i* = 2) : Maximum number of residual computations allowed for refinement.

Default 10

Aggressive Set to 100 to permit convergence using approximate factorizations or factorizations other than *LU*. If the factorization uses a technique other than Gaussian elimination, the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params(*la_linrx_cwise_i* = 3) : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.

Output Parameters

<i>x</i>	<p>REAL for <i>sgbsvxx</i> DOUBLE PRECISION for <i>dgbvsvxx</i> COMPLEX for <i>cgbsvxx</i> DOUBLE COMPLEX for <i>zgbvsvxx</i>. Array, DIMENSION (<i>ldx</i>, *). If <i>info</i> = 0, the array <i>x</i> contains the solution <i>n</i>-by-<i>nrhs</i> matrix <i>x</i> to the <i>original</i> system of equations. Note that <i>A</i> and <i>B</i> are modified on exit if <i>equed</i> ≠ 'N', and the solution to the <i>equilibrated</i> system is: $\text{inv}(\text{diag}(c)) * X$, if <i>trans</i> = 'N' and <i>equed</i> = 'C' or 'B'; or $\text{inv}(\text{diag}(r)) * X$, if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'R' or 'B'. The second dimension of <i>x</i> must be at least $\max(1, nrhs)$.</p>
<i>ab</i>	<p>Array <i>ab</i> is not modified on exit if <i>fact</i> = 'F' or 'N', or if <i>fact</i> = 'E' and <i>equed</i> = 'N'. If <i>equed</i> ≠ 'N', <i>A</i> is scaled on exit as follows: <i>equed</i> = 'R': $A = \text{diag}(r) * A$ <i>equed</i> = 'C': $A = A * \text{diag}(c)$ <i>equed</i> = 'B': $A = \text{diag}(r) * A * \text{diag}(c)$.</p>
<i>afb</i>	<p>If <i>fact</i> = 'N' or 'E', then <i>afb</i> is an output argument and on exit returns the factors <i>L</i> and <i>U</i> from the factorization $A = PLU$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E').</p>
<i>b</i>	<p>Overwritten by $\text{diag}(r) * B$ if <i>trans</i> = 'N' and <i>equed</i> = 'R' or 'B'; overwritten by <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'C' or 'B'; not changed if <i>equed</i> = 'N'.</p>
<i>r, c</i>	<p>These arrays are output arguments if <i>fact</i> ≠ 'F'. Each element of these arrays is a power of the radix. See the description of <i>r, c</i> in <i>Input Arguments</i> section.</p>
<i>rcond</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors.</p>

Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision, in particular, if $rcond = 0$, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.

rpvgrw

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Contains the reciprocal pivot growth factor $norm(A)/norm(U)$. The *max absolute element* norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution x , estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < info \leq n$, this parameter contains the reciprocal pivot growth factor for the leading $info$ columns of A . In *?gbsvx*, this quantity is returned in *work(1)*.

berr

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

err_bnds_norm

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION ($nrhs, n_err_bnds$). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:
 Normwise relative error in the i -th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in `err_bnds_norm(i, :)` corresponds to the *i*-th right-hand side.

The second index in `err_bnds_norm(:, err)` contains the following three fields:

- `err=1` "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision flavors.
- `err=2` "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
- `err=3` Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\text{sqrt}(n) * \text{slamch}(\epsilon)$ for single precision flavors and $\text{sqrt}(n) * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix *z*. Let $z = s * a$, where *s* scales each row by a power of the radix so all absolute row sums of *z* are approximately 1.

`err_bnds_comp`

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the *i*-th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side *i*, on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params*(3) = 0.0), then *err_bnds_comp* is not accessed. If *n_err_bnds* < 3, then at most the first (:, *n_err_bnds*) entries are returned.

The first index in *err_bnds_comp*(*i*, :) corresponds to the *i*-th right-hand side.

The second index in *err_bnds_comp*(:, *err*) contains the following three fields:

- err*=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.
- err*=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

<i>err=3</i>	<p>Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z. Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.</p>
<i>ipiv</i>	<p>If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the original matrix A (if <i>fact</i> = 'N') or of the equilibrated matrix A (if <i>fact</i> = 'E').</p>
<i>equed</i>	<p>If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).</p>
<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful. The solution to every right-hand side is guaranteed. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value. If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; <i>rcond</i> = 0 is returned. If <i>info</i> = $n + j$: The solution corresponding to the <i>j</i>-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides <i>k</i> with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $\text{params}(3) = 0.0$, then the <i>j</i>-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest <i>j</i> such that $\text{err_bnds_norm}(j, 1)$</p>

= 0.0 or `err_bnds_comp(j,1) = 0.0`. See the definition of `err_bnds_norm(; ,1)` and `err_bnds_comp(; ,1)`. To get information about all of the right-hand sides, check `err_bnds_norm` or `err_bnds_comp`.

?gtsv

Computes the solution to the system of linear equations with a tridiagonal matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sgtsv( n, nrhs, dl, d, du, b, ldb, info )
call dgtsv( n, nrhs, dl, d, du, b, ldb, info )
call cgtsv( n, nrhs, dl, d, du, b, ldb, info )
call zgtsv( n, nrhs, dl, d, du, b, ldb, info )
```

Fortran 95:

```
call gtsv( dl, d, du, b [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the system of linear equations $A * X = B$, where A is an n -by- n tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of x are the corresponding solutions. The routine uses Gaussian elimination with partial pivoting.

Note that the equation $A^T * X = B$ may be solved by interchanging the order of the arguments `du` and `dl`.

Input Parameters

<code>n</code>	INTEGER. The order of A , the number of rows in B ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.

d1, d, du, b REAL for `sgtsv`
 DOUBLE PRECISION for `dgtsv`
 COMPLEX for `cgtsv`
 DOUBLE COMPLEX for `zgtsv`.
 Arrays: $d1(n - 1)$, $d(n)$, $du(n - 1)$, $b(ldb, *)$.
 The array *d1* contains the $(n - 1)$ subdiagonal elements of *A*.
 The array *d* contains the diagonal elements of *A*.
 The array *du* contains the $(n - 1)$ superdiagonal elements of *A*.
 The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations. The second dimension of *b* must be at least $\max(1, nrhs)$.

ldb INTEGER. The first dimension of *b*; $ldb \geq \max(1, n)$.

Output Parameters

d1 Overwritten by the $(n-2)$ elements of the second superdiagonal of the upper triangular matrix *U* from the *LU* factorization of *A*. These elements are stored in $d1(1), \dots, d1(n-2)$.

d Overwritten by the *n* diagonal elements of *U*.

du Overwritten by the $(n-1)$ elements of the first superdiagonal of *U*.

b Overwritten by the solution matrix *x*.

info INTEGER. If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, $U(i, i)$ is exactly zero, and the solution has not been computed. The factorization has not been completed unless $i = n$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtsv` interface are as follows:

d1 Holds the vector of length $(n-1)$.
d Holds the vector of length *n*.
d1 Holds the vector of length $(n-1)$.
b Holds the matrix *B* of size $(n, nrhs)$.

?gtsvx

Computes the solution to the real or complex system of linear equations with a tridiagonal matrix A and multiple right-hand sides, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sgtsvx( fact, trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb,
x, ldx, rcond, ferr, berr, work, iwork, info )
```

```
call dgtsvx( fact, trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb,
x, ldx, rcond, ferr, berr, work, iwork, info )
```

```
call cgtsvx( fact, trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb,
x, ldx, rcond, ferr, berr, work, rwork, info )
```

```
call zgtsvx( fact, trans, n, nrhs, dl, d, du, dlf, df, duf, du2, ipiv, b, ldb,
x, ldx, rcond, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call gtsvx( dl, d, du, b, x [,dlf] [,df] [,duf] [,du2] [,ipiv] [,fact] [,trans]
[,ferr] [,berr] [,rcond] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine uses the LU factorization to compute the solution to a real or complex system of linear equations $A^*X = B$, $A^T*X = B$, or $A^H*X = B$, where A is a tridiagonal matrix of order n , the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?gtsvx performs the following steps:

1. If `fact = 'N'`, the LU decomposition is used to factor the matrix A as $A = L*U$, where L is a product of permutation and unit lower bidiagonal matrices and U is an upper triangular matrix with nonzeros in only the main diagonal and first two superdiagonals.

2. If some $U_{i,i} = 0$, so that U is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n + 1$ is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
3. The system of equations is solved for x using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

<i>fact</i>	<p>CHARACTER*1. Must be 'F' or 'N'.</p> <p>Specifies whether or not the factored form of the matrix A has been supplied on entry.</p> <p>If <i>fact</i> = 'F': on entry, <i>dlf</i>, <i>df</i>, <i>duf</i>, <i>du2</i>, and <i>ipiv</i> contain the factored form of A; arrays <i>dl</i>, <i>d</i>, <i>du</i>, <i>dlf</i>, <i>df</i>, <i>duf</i>, <i>du2</i>, and <i>ipiv</i> will not be modified.</p> <p>If <i>fact</i> = 'N', the matrix A will be copied to <i>dlf</i>, <i>df</i>, and <i>duf</i> and factored.</p>
<i>trans</i>	<p>CHARACTER*1. Must be 'N', 'T', or 'C'.</p> <p>Specifies the form of the system of equations:</p> <p>If <i>trans</i> = 'N', the system has the form $A^*X = B$ (No transpose).</p> <p>If <i>trans</i> = 'T', the system has the form $A^T * X = B$ (Transpose).</p> <p>If <i>trans</i> = 'C', the system has the form $A^H * X = B$ (Conjugate transpose).</p>
<i>n</i>	<p>INTEGER. The number of linear equations, the order of the matrix A;</p> <p>$n \geq 0$.</p>
<i>nrhs</i>	<p>INTEGER. The number of right hand sides, the number of columns of the matrices B and X; $nrhs \geq 0$.</p>
<i>dl,d,du,dlf,df,duf,du2,b,x,work</i>	<p>REAL for sgtsvx</p> <p>DOUBLE PRECISION for dgtsvx</p> <p>COMPLEX for cgtsvx</p> <p>DOUBLE COMPLEX for zgtsvx.</p> <p>Arrays:</p> <p><i>dl</i>, dimension $(n - 1)$, contains the subdiagonal elements of A.</p> <p><i>d</i>, dimension (n), contains the diagonal elements of A.</p> <p><i>du</i>, dimension $(n - 1)$, contains the superdiagonal elements of A.</p>

	<i>d1f</i> , dimension $(n-1)$. If <i>fact</i> = 'F' , then <i>d1f</i> is an input argument and on entry contains the $(n-1)$ multipliers that define the matrix <i>L</i> from the <i>LU</i> factorization of <i>A</i> as computed by ?gttrf .
	<i>df</i> , dimension (n) . If <i>fact</i> = 'F' , then <i>df</i> is an input argument and on entry contains the n diagonal elements of the upper triangular matrix <i>U</i> from the <i>LU</i> factorization of <i>A</i> .
	<i>d1f</i> , dimension $(n-1)$. If <i>fact</i> = 'F' , then <i>d1f</i> is an input argument and on entry contains the $(n-1)$ elements of the first superdiagonal of <i>U</i> .
	<i>du2</i> , dimension $(n-2)$. If <i>fact</i> = 'F' , then <i>du2</i> is an input argument and on entry contains the $(n-2)$ elements of the second superdiagonal of <i>U</i> .
	<i>b</i> (<i>ldb</i> *) contains the right-hand side matrix <i>B</i> . The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.
	<i>x</i> (<i>ldx</i> *) contains the solution matrix <i>X</i> . The second dimension of <i>x</i> must be at least $\max(1, nrhs)$.
	<i>work</i> (*) is a workspace array; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of <i>x</i> ; $ldx \geq \max(1, n)$.
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. If <i>fact</i> = 'F' , then <i>ipiv</i> is an input argument and on entry contains the pivot indices, as returned by ?gttrf .
<i>iwork</i>	INTEGER. Workspace array, DIMENSION (n) . Used for real flavors only.
<i>rwork</i>	REAL for <i>cgtsvx</i> DOUBLE PRECISION for <i>zgtsvx</i> . Workspace array, DIMENSION (n) . Used for complex flavors only.

Output Parameters

<i>x</i>	REAL for <i>sgtsvx</i> DOUBLE PRECISION for <i>dgtsvx</i> COMPLEX for <i>cgtsvx</i> DOUBLE COMPLEX for <i>zgtsvx</i> . Array, DIMENSION $(ldx, *)$.
----------	--

	If $info = 0$ or $info = n+1$, the array x contains the solution matrix X . The second dimension of x must be at least $\max(1, nrhs)$.
<i>d1f</i>	If $fact = 'N'$, then <i>d1f</i> is an output argument and on exit contains the $(n-1)$ multipliers that define the matrix L from the LU factorization of A .
<i>df</i>	If $fact = 'N'$, then <i>df</i> is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A .
<i>duf</i>	If $fact = 'N'$, then <i>duf</i> is an output argument and on exit contains the $(n-1)$ elements of the first superdiagonal of U .
<i>du2</i>	If $fact = 'N'$, then <i>du2</i> is an output argument and on exit contains the $(n-2)$ elements of the second superdiagonal of U .
<i>ipiv</i>	The array <i>ipiv</i> is an output argument if $fact = 'N'$ and, on exit, contains the pivot indices from the factorization $A = L*U$; row i of the matrix was interchanged with row $ipiv(i)$. The value of $ipiv(i)$ will always be i or $i+1$; $ipiv(i)=i$ indicates a row interchange was not required.
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix A . If <i>rcond</i> is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.
<i>ferr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j -th column of the solution matrix X). If x_{true} is the true solution corresponding to $x(j)$, $ferr(j)$ is an estimated upper bound for the magnitude of the largest element in $(x(j) - x_{true})$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

info INTEGER. If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, and $i \leq n$, then $U(i, i)$ is exactly zero. The factorization has not been completed unless $i = n$, but the factor U is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned. If *info* = *i*, and $i = n + 1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gtsvx` interface are as follows:

<i>dl</i>	Holds the vector of length $(n-1)$.
<i>d</i>	Holds the vector of length n .
<i>du</i>	Holds the vector of length $(n-1)$.
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>dlf</i>	Holds the vector of length $(n-1)$.
<i>df</i>	Holds the vector of length n .
<i>duf</i>	Holds the vector of length $(n-1)$.
<i>du2</i>	Holds the vector of length $(n-2)$.
<i>ipiv</i>	Holds the vector of length n .
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.

<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then the arguments <i>dlf</i> , <i>df</i> , <i>duf</i> , <i>du2</i> , and <i>ipiv</i> must be present; otherwise, an error is returned.
<i>trans</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.

?dtsvb

Computes the solution to the system of linear equations with a diagonally dominant tridiagonal matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sdtsvb( n, nrhs, dl, d, du, b, ldb, info )
call ddtsvb( n, nrhs, dl, d, du, b, ldb, info )
call cdtsvb( n, nrhs, dl, d, du, b, ldb, info )
call zdtsvb( n, nrhs, dl, d, du, b, ldb, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The ?dtsvb routine solves a system of linear equations $A^T X = B$ for X , where A is an n -by- n diagonally dominant tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions. The routine uses the BABE (Burning At Both Ends) algorithm.

Note that the equation $A^T X = B$ may be solved by interchanging the order of the arguments du and dl .

Input Parameters

<i>n</i>	INTEGER. The order of A , the number of rows in B ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>dl, d, du, b</i>	REAL for sdtsvb DOUBLE PRECISION for ddtsvb

COMPLEX for `cdtsvb`
 DOUBLE COMPLEX for `zdtsvb`.
 Arrays: $d1(n - 1)$, $d(n)$, $du(n - 1)$, $b(ldb, *)$.
 The array $d1$ contains the $(n - 1)$ subdiagonal elements of A .
 The array d contains the diagonal elements of A .
 The array du contains the $(n - 1)$ superdiagonal elements of A .
 The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

ldb INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

$d1$ Overwritten by the $(n-1)$ elements of the subdiagonal of the lower triangular matrices L_1, L_2 from the factorization of A .
 d Overwritten by the n diagonal element reciprocals of U .
 b Overwritten by the solution matrix X .
 $info$ INTEGER. If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info = i$, u_{ii} is exactly zero, and the solution has not been computed. The factorization has not been completed unless $i = n$.

Application Notes

A diagonally dominant tridiagonal system is defined such that $|d_i| > |d1_{i-1}| + |du_i|$ for any i :

$$1 < i < n, \text{ and } |d_1| > |du_1|, |d_n| > |d1_{n-1}|$$

The underlying BABE algorithm is designed for diagonally dominant systems. Such systems have no numerical stability issue unlike the canonical systems that use elimination with partial pivoting (see [?gtsv](#)). The diagonally dominant systems are much faster than the canonical systems.

**NOTE.**

- The current implementation of BABE has a potential accuracy issue on very small or large data close to the underflow or overflow threshold respectively. Scale the matrix before applying the solver in the case of such input data.
- Applying the ?dtsvb factorization to non-diagonally dominant systems may lead to an accuracy loss, or false singularity detected due to no pivoting.

?posv

Computes the solution to the system of linear equations with a symmetric or Hermitian positive-definite matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sposv( uplo, n, nrhs, a, lda, b, ldb, info )
call dposv( uplo, n, nrhs, a, lda, b, ldb, info )
call cposv( uplo, n, nrhs, a, lda, b, ldb, info )
call zposv( uplo, n, nrhs, a, lda, b, ldb, info )
call dsposv( uplo, n, nrhs, a, lda, b, ldb, x, ldx, work, swork, iter, info
)
call zcposv( uplo, n, nrhs, a, lda, b, ldb, x, ldx, work, swork, rwork, iter,
info )
```

Fortran 95:

```
call posv( a, b [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the real or complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric/Hermitian positive-definite matrix, the columns of matrix B are individual right-hand sides, and the columns of x are the corresponding solutions.

The Cholesky decomposition is used to factor A as

$A = U^T * U$ (real flavors) and $A = U^H * U$ (complex flavors), if $uplo = 'U'$

or $A = L * L^T$ (real flavors) and $A = L * L^H$ (complex flavors), if $uplo = 'L'$,

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A^*X = B$.

The `dsposv` and `zcpovs` are mixed precision iterative refinement subroutines for exploiting fast single precision hardware. They first attempt to factorize the matrix in single precision (`dsposv`) or single complex precision (`zcpovs`) and use this factorization within an iterative refinement procedure to produce a solution with double precision (`dsposv`) / double complex precision (`zcpovs`) normwise backward error quality (see below). If the approach fails, the method switches to a double precision or double complex precision factorization respectively and computes the solution.

The iterative refinement is not going to be a winning strategy if the ratio single precision/COMPLEX performance over double precision/DOUBLE COMPLEX performance is too small. A reasonable strategy should take the number of right-hand sides and the size of the matrix into account. This might be done with a call to `ilaenv` in the future. At present, iterative refinement is implemented.

The iterative refinement process is stopped if

`iter > itermax`

or for all the right-hand sides:

`rnmr < sqrt(n)*xnrm*anrm*eps*bwdmax,`

where

- `iter` is the number of the current iteration in the iterative refinement process
- `rnmr` is the infinity-norm of the residual
- `xnrm` is the infinity-norm of the solution
- `anrm` is the infinity-operator-norm of the matrix A
- `eps` is the machine epsilon returned by `dlamch` ('Epsilon').

The values `itermax` and `bwdmax` are fixed to 30 and 1.0d+00 respectively.

Input Parameters

`uplo` CHARACTER*1. Must be 'U' or 'L'.

	Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored.
n	INTEGER. The order of matrix A ; $n \geq 0$.
$nrhs$	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
a, b	REAL for $sposv$ DOUBLE PRECISION for $dposv$ and $dsposv$. COMPLEX for $cposv$ DOUBLE COMPLEX for $zposv$ and $zcposv$. Arrays: $a(lda, *)$, $b ldb, *)$. The array a contains the upper or the lower triangular part of the matrix A (see $uplo$). The second dimension of a must be at least $\max(1, n)$. Note that in the case of $zcposv$ the imaginary parts of the diagonal elements need not be set and are assumed to be zero. The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.
lda	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
ldb	INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.
ldx	INTEGER. The leading dimension of the array x ; $ldx \geq \max(1, n)$.
$work$	DOUBLE PRECISION for $dsposv$ DOUBLE COMPLEX for $zcposv$. Workspace array, DIMENSION $(n*nrhs)$. This array is used to hold the residual vectors.
$swork$	REAL for $dsgesv$ COMPLEX for $zcgsv$. Workspace array, DIMENSION $(n*(n+nrhs))$. This array is used to use the single precision matrix and the right-hand sides or solutions in single precision.
$rwork$	DOUBLE PRECISION. Workspace array, DIMENSION (n) .

Output Parameters

<i>a</i>	<p>If <i>info</i> = 0, the upper or lower triangular part of <i>a</i> is overwritten by the Cholesky factor <i>U</i> or <i>L</i>, as specified by <i>uplo</i>.</p> <p>If iterative refinement has been successfully used (<i>info</i>= 0 and <i>iter</i> ≥ 0), then <i>A</i> is unchanged.</p> <p>If double precision factorization has been used (<i>info</i>= 0 and <i>iter</i> < 0), then the array <i>A</i> contains the factors <i>L</i> and <i>U</i> from the Cholesky factorization; the unit diagonal elements of <i>L</i> are not stored.</p>
<i>b</i>	Overwritten by the solution matrix <i>x</i> .
<i>ipiv</i>	<p>INTEGER.</p> <p>Array, DIMENSION at least $\max(1, n)$. The pivot indices that define the permutation matrix <i>P</i>; row <i>i</i> of the matrix was interchanged with row <i>ipiv</i>(<i>i</i>). Corresponds to the single precision factorization (if <i>info</i>= 0 and <i>iter</i> ≥ 0) or the double precision factorization (if <i>info</i>= 0 and <i>iter</i> < 0).</p>
<i>x</i>	<p>DOUBLE PRECISION for <i>dsposv</i></p> <p>DOUBLE COMPLEX for <i>zcposv</i>.</p> <p>Array, DIMENSION (<i>ldx</i>, <i>nrhs</i>). If <i>info</i> = 0, contains the <i>n</i>-by-<i>nrhs</i> solution matrix <i>x</i>.</p>
<i>iter</i>	<p>INTEGER.</p> <p>If <i>iter</i> < 0: iterative refinement has failed, double precision factorization has been performed</p> <ul style="list-style-type: none"> • If <i>iter</i> = -1: the routine fell back to full precision for implementation- or machine-specific reason • If <i>iter</i> = -2: narrowing the precision induced an overflow, the routine fell back to full precision • If <i>iter</i> = -3: failure of <i>spotrf</i> for <i>dsposv</i>, or <i>cpotrf</i> for <i>zcposv</i> • If <i>iter</i> = -31: stop the iterative refinement after the 30th iteration. <p>If <i>iter</i> > 0: iterative refinement has been successfully used. Returns the number of iterations.</p>
<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive definite, so the factorization could not be completed, and the solution has not been computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `posv` interface are as follows:

a	Holds the matrix A of size (n, n) .
b	Holds the matrix B of size $(n, nrhs)$.
$uplo$	Must be 'U' or 'L'. The default value is 'U'.

?posvx

Uses the Cholesky factorization to compute the solution to the system of linear equations with a symmetric or Hermitian positive-definite matrix A , and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sposvx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx,  
rcond, ferr, berr, work, iwork, info )
```

```
call dposvx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx,  
rcond, ferr, berr, work, iwork, info )
```

```
call cposvx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx,  
rcond, ferr, berr, work, rwork, info )
```

```
call zposvx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx,  
rcond, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call posvx( a, b, x [,uplo] [,af] [,fact] [,equed] [,s] [,ferr] [,berr] [,rcond]  
[,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine uses the *Cholesky* factorization $A=U^T*U$ (real flavors) / $A=U^H*U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where A is a n -by- n real symmetric/Hermitian positive definite matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?posvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors s are computed to equilibrate the system:

$$diag(s)*A*diag(s)*inv(diag(s))*X = diag(s)*B.$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(s)*A*diag(s)$ and B by $diag(s)*B$.

2. If `fact = 'N'` or `'E'`, the Cholesky decomposition is used to factor the matrix A (after equilibration if `fact = 'E'`) as

$$A = U^T*U \text{ (real), } A = U^H*U \text{ (complex), if } uplo = 'U',$$

$$\text{or } A = L*L^T \text{ (real), } A = L*L^H \text{ (complex), if } uplo = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i -by- i principal minor is not positive-definite, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n + 1` is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
4. The system of equations is solved for x using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix x is premultiplied by $diag(s)$ so that it solves the original system before equilibration.

Input Parameters

`fact` CHARACTER*1. Must be 'F', 'N', or 'E'.

	<p>Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.</p> <p>If $fact = 'F'$: on entry, af contains the factored form of A. If $equed = 'Y'$, the matrix A has been equilibrated with scaling factors given by s.</p> <p>a and af will not be modified.</p> <p>If $fact = 'N'$, the matrix A will be copied to af and factored.</p> <p>If $fact = 'E'$, the matrix A will be equilibrated if necessary, then copied to af and factored.</p>
$uplo$	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of A is stored:</p> <p>If $uplo = 'U'$, the upper triangle of A is stored.</p> <p>If $uplo = 'L'$, the lower triangle of A is stored.</p>
n	<p>INTEGER. The order of matrix A; $n \geq 0$.</p>
$nrhs$	<p>INTEGER. The number of right-hand sides, the number of columns in B; $nrhs \geq 0$.</p>
$a, af, b, work$	<p>REAL for $sposvx$ DOUBLE PRECISION for $dposvx$ COMPLEX for $cposvx$ DOUBLE COMPLEX for $zposvx$.</p> <p>Arrays: $a(lda,*)$, $af(ldaf,*)$, $b(ldb,*)$, $work(*)$.</p> <p>The array a contains the matrix A as specified by $uplo$. If $fact = 'F'$ and $equed = 'Y'$, then A must have been equilibrated by the scaling factors in s, and a must contain the equilibrated matrix $diag(s)*A*diag(s)$. The second dimension of a must be at least $\max(1, n)$.</p> <p>The array af is an input argument if $fact = 'F'$. It contains the triangular factor U or L from the Cholesky factorization of A in the same storage format as A. If $equed$ is not 'N', then af is the factored form of the equilibrated matrix $diag(s)*A*diag(s)$. The second dimension of af must be at least $\max(1, n)$.</p> <p>The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.</p>

	<i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldaf</i>	INTEGER. The first dimension of <i>af</i> ; $ldaf \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>equed</i>	CHARACTER*1. Must be 'N' or 'Y'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: if <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N'); if <i>equed</i> = 'Y', equilibration was done, that is, <i>A</i> has been replaced by $diag(s)*A*diag(s)$.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i> . This array is an input argument if <i>fact</i> = 'F' only; otherwise it is an output argument. If <i>equed</i> = 'N', <i>s</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive.
<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.
<i>rwork</i>	REAL for cposvx DOUBLE PRECISION for zposvx. Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

<i>x</i>	REAL for sposvx DOUBLE PRECISION for dposvx COMPLEX for cposvx DOUBLE COMPLEX for zposvx. Array, DIMENSION (<i>ldx</i> , *).
----------	---

	<p>If $info = 0$ or $info = n+1$, the array x contains the solution matrix x to the <i>original</i> system of equations. Note that if $equed = 'Y'$, A and B are modified on exit, and the solution to the equilibrated system is $inv(diag(s))*X$. The second dimension of x must be at least $max(1, nrhs)$.</p>
<i>a</i>	<p>Array a is not modified on exit if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$. If $fact = 'E'$ and $equed = 'Y'$, A is overwritten by $diag(s)*A*diag(s)$.</p>
<i>af</i>	<p>If $fact = 'N'$ or $'E'$, then af is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A=U**T*U$ or $A=L*L**T$ (real routines), $A=U**H*U$ or $A=L*L**H$ (complex routines) of the original matrix A (if $fact = 'N'$), or of the equilibrated matrix A (if $fact = 'E'$). See the description of a for the form of the equilibrated matrix.</p>
<i>b</i>	<p>Overwritten by $diag(s)*B$, if $equed = 'Y'$; not changed if $equed = 'N'$.</p>
<i>s</i>	<p>This array is an output argument if $fact \neq 'F'$. See the description of s in <i>Input Arguments</i> section.</p>
<i>rcond</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.</p>
<i>ferr</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j-th column of the solution matrix x). If $xtrue$ is the true solution corresponding to $x(j)$, $ferr(j)$ is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error.</p>
<i>berr</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors.</p>

	Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.
<i>equed</i>	If <i>fact</i> \neq 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , and $i \leq n$, the leading minor of order <i>i</i> (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; <i>rcond</i> = 0 is returned. If <i>info</i> = <i>i</i> , and $i = n + 1$, then U is nonsingular, but <i>rcond</i> is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of <i>rcond</i> would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `posvx` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>af</i>	Holds the matrix AF of size (n, n) .
<i>s</i>	Holds the vector of length n . Default value for each element is $s(i) = 1.0_WP$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N', 'E', or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then <i>af</i> must be present; otherwise, an error is returned.

equed

Must be 'N' or 'Y'. The default value is 'N'.

?posvxx

Uses extra precise iterative refinement to compute the solution to the system of linear equations with a symmetric or Hermitian positive-definite matrix A applying the Cholesky factorization.

Syntax

FORTRAN 77:

```
call sposvxx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx,
             rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams,
             params, work, iwork, info )
```

```
call dposvxx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx,
             rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams,
             params, work, iwork, info )
```

```
call cposvxx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx,
             rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams,
             params, work, rwork, info )
```

```
call zposvxx( fact, uplo, n, nrhs, a, lda, af, ldaf, equed, s, b, ldb, x, ldx,
             rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams,
             params, work, rwork, info )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface and in `mkl_lapack.h` for C interface.

The routine uses the *Cholesky* factorization $A=U^T*U$ (real flavors) / $A=U^H*U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where A is an n -by- n real symmetric/Hermitian positive definite matrix, the columns of matrix B are individual right-hand sides, and the columns of x are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\text{eps})$, where eps is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\epsilon)$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine `?posvxx` performs the following steps:

1. If *fact* = 'E', scaling factors are computed to equilibrate the system:

$$\text{diag}(s) * A * \text{diag}(s) * \text{inv}(\text{diag}(s)) * X = \text{diag}(s) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix *A*, but if equilibration is used, *A* is overwritten by $\text{diag}(s) * A * \text{diag}(s)$ and *B* by $\text{diag}(s) * B$.

2. If *fact* = 'N' or 'E', the Cholesky decomposition is used to factor the matrix *A* (after equilibration if *fact* = 'E') as

$$A = U^T * U \text{ (real)}, A = U^H * U \text{ (complex)}, \text{ if } \text{uplo} = \text{'U'},$$

$$\text{or } A = L * L^T \text{ (real)}, A = L * L^H \text{ (complex)}, \text{ if } \text{uplo} = \text{'L'},$$

where *U* is an upper triangular matrix and *L* is a lower triangular matrix.

3. If the leading *i*-by-*i* principal minor is not positive-definite, the routine returns with *info* = *i*. Otherwise, the factored form of *A* is used to estimate the condition number of the matrix *A* (see the *rcond* parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for *x* and compute error bounds.
4. The system of equations is solved for *x* using the factored form of *A*.
5. By default, unless `params(la_linrx_itref_i)` is set to zero, the routine applies iterative refinement to get a small error and error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix *x* is premultiplied by $\text{diag}(s)$ so that it solves the original system before equilibration.

Input Parameters

fact CHARACTER*1. Must be 'F', 'N', or 'E'.
Specifies whether or not the factored form of the matrix *A* is supplied on entry, and if not, whether the matrix *A* should be equilibrated before it is factored.

If *fact* = 'F', on entry, *af* contains the factored form of *A*. If *equed* is not 'N', the matrix *A* has been equilibrated with scaling factors given by *s*. Parameters *a* and *af* are not modified.

If *fact* = 'N', the matrix *A* will be copied to *af* and factored.

If *fact* = 'E', the matrix *A* will be equilibrated, if necessary, copied to *af* and factored.

uplo CHARACTER*1. Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of *A* is stored:
If *uplo* = 'U', the upper triangle of *A* is stored.
If *uplo* = 'L', the lower triangle of *A* is stored.

n INTEGER. The number of linear equations; the order of the matrix *A*; $n \geq 0$.

nrhs INTEGER. The number of right-hand sides; the number of columns of the matrices *B* and *X*; $nrhs \geq 0$.

a, af, b, work REAL for *sposvxx*
DOUBLE PRECISION for *dposvxx*
COMPLEX for *cposvxx*
DOUBLE COMPLEX for *zposvxx*.
Arrays: *a(lda,*)*, *af(ldaf,*)*, *b(ldb,*)*, *work(*)*.
The array *a* contains the matrix *A* as specified by *uplo*. If *fact* = 'F' and *equed* = 'Y', then *A* must have been equilibrated by the scaling factors in *s*, and *a* must contain the equilibrated matrix $diag(s)*A*diag(s)$. The second dimension of *a* must be at least $\max(1, n)$.
The array *af* is an input argument if *fact* = 'F'. It contains the triangular factor *U* or *L* from the Cholesky factorization of *A* in the same storage format as *A*. If *equed* is not 'N', then *af* is the factored form of the equilibrated matrix $diag(s)*A*diag(s)$. The second dimension of *af* must be at least $\max(1, n)$.
The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations. The second dimension of *b* must be at least $\max(1, nrhs)$.
If *equed* = 'N', *s* is not accessed.

If $fact = 'F'$ and $equed = 'Y'$, each element of s must be positive.

$work(*)$ is a workspace array. The dimension of $work$ must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

lda INTEGER. The first dimension of the array a ; $lda \geq \max(1, n)$.

ldaf INTEGER. The first dimension of the array af ; $ldaf \geq \max(1, n)$.

equed CHARACTER*1. Must be 'N' or 'Y'.
equed is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:
 If $equed = 'N'$, no equilibration was done (always true if $fact = 'N'$).
 if $equed = 'Y'$, both row and column equilibration was done, that is, A has been replaced by $diag(s)*A*diag(s)$.

s REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION (n). The array s contains the scale factors for A . This array is an input argument if $fact = 'F'$ only; otherwise it is an output argument.
 If $equed = 'N'$, s is not accessed.
 If $fact = 'F'$ and $equed = 'Y'$, each element of s must be positive.
 Each element of s should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

ldb INTEGER. The first dimension of the array b ; $ldb \geq \max(1, n)$.

ldx INTEGER. The first dimension of the output array x ; $ldx \geq \max(1, n)$.

<i>n_err_bnds</i>	INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in the <i>Output Arguments</i> section below.
<i>nparams</i>	INTEGER. Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used.
<i>params</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION <i>nparams</i>. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <i>nparams</i> = 0, which prevents the source code from accessing the <i>params</i> argument.</p> <p><i>params</i>(<i>la_linrx_itref_i</i> = 1) : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors).</p> <p>=0.0 No refinement is performed and no error bounds are computed.</p> <p>=1.0 Use the extra-precise refinement algorithm. (Other values are reserved for future use.)</p> <p><i>params</i>(<i>la_linrx_ithresh_i</i> = 2) : Maximum number of residual computations allowed for refinement.</p> <p>Default 10</p> <p>Aggressive Set to 100 to permit convergence using approximate factorizations or factorizations other than <i>LU</i>. If the factorization uses a technique other than Gaussian elimination, the guarantees in <i>err_bnds_norm</i> and <i>err_bnds_comp</i> may no longer be trustworthy.</p>

params(*la_linrx_cwise_i* = 3) : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.

Output Parameters

x REAL for *sposvxx*
DOUBLE PRECISION for *dposvxx*
COMPLEX for *cposvxx*
DOUBLE COMPLEX for *zposvxx*.
Array, DIMENSION (*ldx*, *).
If *info* = 0, the array *x* contains the solution *n*-by-*nrhs* matrix *X* to the original system of equations. Note that *A* and *B* are modified on exit if *equed* ≠ 'N', and the solution to the equilibrated system is:
 $\text{inv}(\text{diag}(s)) * X$.

a Array *a* is not modified on exit if *fact* = 'F' or 'N', or if *fact* = 'E' and *equed* = 'N'.
If *fact* = 'E' and *equed* = 'Y', *A* is overwritten by $\text{diag}(s) * A * \text{diag}(s)$.

af If *fact* = 'N' or 'E', then *af* is an output argument and on exit returns the triangular factor *U* or *L* from the Cholesky factorization $A = U * U^T * U$ or $A = L * L^T * L$ (real routines), $A = U * U^H * U$ or $A = L * L^H * L$ (complex routines) of the original matrix *A* (if *fact* = 'N'), or of the equilibrated matrix *A* (if *fact* = 'E'). See the description of *a* for the form of the equilibrated matrix.

b If *equed* = 'N', *B* is not modified.
If *equed* = 'Y', *B* is overwritten by $\text{diag}(s) * B$.

<i>s</i>	This array is an output argument if <i>fact</i> ≠ 'F'. Each element of this array is a power of the radix. See the description of <i>s</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.
<i>rpvgrw</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Contains the reciprocal pivot growth factor $norm(A)/norm(U)$. The <i>max absolute element</i> norm is used. If this is much less than 1, the stability of the LU factorization of the (equilibrated) matrix <i>A</i> could be poor. This also means that the solution <i>x</i> , estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < info \leq n$, this parameter contains the reciprocal pivot growth factor for the leading <i>info</i> columns of <i>A</i> .
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes $x(j)$ an exact solution.
<i>err_bnds_norm</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>nrhs</i> , <i>n_err_bnds</i>). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows: Normwise relative error in the <i>i</i> -th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in `err_bnds_norm(i, :)` corresponds to the *i*-th right-hand side.

The second index in `err_bnds_norm(:, err)` contains the following three fields:

- `err=1` "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.
- `err=2` "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.
- `err=3` Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix *z*.

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

err_bnds_comp

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:
 Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params*(3) = 0.0), then *err_bnds_comp* is not accessed. If *n_err_bnds* < 3, then at most the first (:, *n_err_bnds*) entries are returned.

The first index in *err_bnds_comp*(i , :) corresponds to the i -th right-hand side.

The second index in *err_bnds_comp*(:, *err*) contains the following three fields:

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double

	precision flavors. This error bound should only be trusted if the previous boolean is true.
<i>err=3</i>	<p>Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold</p> <p>$\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are</p> <p>$1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z.</p> <p>Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.</p>
<i>ipiv</i>	If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the original matrix A (if <i>fact</i> = 'N') or of the equilibrated matrix A (if <i>fact</i> = 'E').
<i>equed</i>	If <i>fact</i> \neq 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful. The solution to every right-hand side is guaranteed.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p> <p>If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; <i>rcond</i> = 0 is returned.</p> <p>If <i>info</i> = $n + j$: The solution corresponding to the <i>j</i>-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides <i>k</i> with $k > j$ may not be guaranteed as well, but only the first such right-hand</p>

side is reported. If a small componentwise error is not requested $params(3) = 0.0$, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that $err_bnds_norm(j,1) = 0.0$ or $err_bnds_comp(j,1) = 0.0$. See the definition of $err_bnds_norm(; ,1)$ and $err_bnds_comp(; ,1)$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

?ppsv

Computes the solution to the system of linear equations with a symmetric (Hermitian) positive definite packed matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sppsv( uplo, n, nrhs, ap, b, ldb, info )
call dpssv( uplo, n, nrhs, ap, b, ldb, info )
call cppsv( uplo, n, nrhs, ap, b, ldb, info )
call zppsv( uplo, n, nrhs, ap, b, ldb, info )
```

Fortran 95:

```
call ppsv( ap, b [,uplo] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine solves for x the real or complex system of linear equations $A * X = B$, where A is an n -by- n real symmetric/Hermitian positive-definite matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of x are the corresponding solutions.

The Cholesky decomposition is used to factor A as

$A = U^T * U$ (real flavors) and $A = U^H * U$ (complex flavors), if `uplo = 'U'`

or $A = L^*L^T$ (real flavors) and $A = L^*L^H$ (complex flavors), if $uplo = 'L'$,

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If $uplo = 'U'$, the upper triangle of A is stored. If $uplo = 'L'$, the lower triangle of A is stored.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>ap, b</i>	REAL for <i>sppsv</i> DOUBLE PRECISION for <i>dppsv</i> COMPLEX for <i>cppsv</i> DOUBLE COMPLEX for <i>zppsv</i> . Arrays: $ap(*)$, $b(ldb,*)$. The array ap contains the upper or the lower triangular part of the matrix A (as specified by $uplo$) in <i>packed storage</i> (see Matrix Storage Schemes). The dimension of ap must be at least $\max(1, n(n+1)/2)$. The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.
<i>ldb</i>	INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

<i>ap</i>	If $info = 0$, the upper or lower triangular part of A in packed storage is overwritten by the Cholesky factor U or L , as specified by $uplo$.
<i>b</i>	Overwritten by the solution matrix X .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution has not been computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ppsv` interface are as follows:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

?ppsvx

Uses the Cholesky factorization to compute the solution to the system of linear equations with a symmetric (Hermitian) positive definite packed matrix A , and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sppsvx( fact, uplo, n, nrhs, ap, afp, equed, s, b, ldb, x, ldx, rcond,
ferr, berr, work, iwork, info )
```

```
call dppsvx( fact, uplo, n, nrhs, ap, afp, equed, s, b, ldb, x, ldx, rcond,
ferr, berr, work, iwork, info )
```

```
call cppsvx( fact, uplo, n, nrhs, ap, afp, equed, s, b, ldb, x, ldx, rcond,
ferr, berr, work, rwork, info )
```

```
call zppsvx( fact, uplo, n, nrhs, ap, afp, equed, s, b, ldb, x, ldx, rcond,
ferr, berr, work, rwork, info )
```

Fortran 95:

```
call ppsvx( ap, b, x [,uplo] [,af] [,fact] [,equed] [,s] [,ferr] [,berr]
[,rcond] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine uses the Cholesky factorization $A=U^T*U$ (real flavors) / $A=U^H*U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where A is a n -by- n symmetric or Hermitian positive-definite matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?ppsvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors s are computed to equilibrate the system:

$$diag(s)*A*diag(s)*inv(diag(s))*X = diag(s)*B.$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(s)*A*diag(s)$ and B by $diag(s)*B$.

2. If `fact = 'N'` or `'E'`, the Cholesky decomposition is used to factor the matrix A (after equilibration if `fact = 'E'`) as

$$A = U^T*U \text{ (real), } A = U^H*U \text{ (complex), if } uplo = 'U',$$

$$\text{or } A = L*L^T \text{ (real), } A = L*L^H \text{ (complex), if } uplo = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i -by- i principal minor is not positive-definite, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n+1` is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $diag(s)$ so that it solves the original system before equilibration.

Input Parameters

`fact` CHARACTER*1. Must be 'F', 'N', or 'E'.
Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

	<p>If <i>fact</i> = 'F': on entry, <i>afp</i> contains the factored form of <i>A</i>. If <i>equed</i> = 'Y', the matrix <i>A</i> has been equilibrated with scaling factors given by <i>s</i>.</p> <p><i>ap</i> and <i>afp</i> will not be modified.</p> <p>If <i>fact</i> = 'N', the matrix <i>A</i> will be copied to <i>afp</i> and factored.</p> <p>If <i>fact</i> = 'E', the matrix <i>A</i> will be equilibrated if necessary, then copied to <i>afp</i> and factored.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of <i>A</i> is stored:</p> <p>If <i>uplo</i> = 'U', the upper triangle of <i>A</i> is stored.</p> <p>If <i>uplo</i> = 'L', the lower triangle of <i>A</i> is stored.</p>
<i>n</i>	<p>INTEGER. The order of matrix <i>A</i>; $n \geq 0$.</p>
<i>nrhs</i>	<p>INTEGER. The number of right-hand sides; the number of columns in <i>B</i>; $nrhs \geq 0$.</p>
<i>ap,afp,b,work</i>	<p>REAL for <i>sppsvx</i> DOUBLE PRECISION for <i>dppsvx</i> COMPLEX for <i>cppsvx</i> DOUBLE COMPLEX for <i>zppsvx</i>.</p> <p>Arrays: <i>ap</i>(*), <i>afp</i>(*), <i>b</i>(<i>ldb</i>,*), <i>work</i>(*).</p> <p>The array <i>ap</i> contains the upper or lower triangle of the original symmetric/Hermitian matrix <i>A</i> in <i>packed storage</i> (see Matrix Storage Schemes). In case when <i>fact</i> = 'F' and <i>equed</i> = 'Y', <i>ap</i> must contain the equilibrated matrix $diag(s)*A*diag(s)$.</p> <p>The array <i>afp</i> is an input argument if <i>fact</i> = 'F' and contains the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization of <i>A</i> in the same storage format as <i>A</i>. If <i>equed</i> is not 'N', then <i>afp</i> is the factored form of the equilibrated matrix <i>A</i>.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations.</p> <p><i>work</i>(*) is a workspace array.</p> <p>The dimension of arrays <i>ap</i> and <i>afp</i> must be at least $\max(1, n(n+1)/2)$; the second dimension of <i>b</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.</p>
<i>ldb</i>	<p>INTEGER. The first dimension of <i>b</i>; $ldb \geq \max(1, n)$.</p>
<i>equed</i>	<p>CHARACTER*1. Must be 'N' or 'Y'.</p>

equed is an input argument if *fact* = 'F'. It specifies the form of equilibration that was done:
 if *equed* = 'N', no equilibration was done (always true if *fact* = 'N');
 if *equed* = 'Y', equilibration was done, that is, *A* has been replaced by *diag(s)A*diag(s)*.

s REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION (*n*). The array *s* contains the scale factors for *A*. This array is an input argument if *fact* = 'F' only; otherwise it is an output argument.
 If *equed* = 'N', *s* is not accessed.
 If *fact* = 'F' and *equed* = 'Y', each element of *s* must be positive.

ldx INTEGER. The first dimension of the output array *x*; $ldx \geq \max(1, n)$.

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork REAL for cppsvx;
 DOUBLE PRECISION for zppsvox.
 Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

x REAL for spsvx
 DOUBLE PRECISION for dpsvx
 COMPLEX for cppsvox
 DOUBLE COMPLEX for zppsvox.
 Array, DIMENSION (*ldx*, *).
 If *info* = 0 or *info* = *n*+1, the array *x* contains the solution matrix *x* to the *original* system of equations. Note that if *equed* = 'Y', *A* and *B* are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(s)) * X$. The second dimension of *x* must be at least $\max(1, nrhs)$.

ap Array *ap* is not modified on exit if *fact* = 'F' or 'N', or if *fact* = 'E' and *equed* = 'N'.
 If *fact* = 'E' and *equed* = 'Y', *A* is overwritten by $\text{diag}(s) * A * \text{diag}(s)$.

<i>afp</i>	If <i>fact</i> = 'N' or 'E', then <i>afp</i> is an output argument and on exit returns the triangular factor <i>U</i> or <i>L</i> from the Cholesky factorization $A=U^T*U$ or $A=L*L^T$ (real routines), $A=U^H*U$ or $A=L*L^H$ (complex routines) of the original matrix <i>A</i> (if <i>fact</i> = 'N'), or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E'). See the description of <i>ap</i> for the form of the equilibrated matrix.
<i>b</i>	Overwritten by $diag(s)*B$, if <i>equed</i> = 'Y'; not changed if <i>equed</i> = 'N'.
<i>s</i>	This array is an output argument if <i>fact</i> ≠ 'F'. See the description of <i>s</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.
<i>ferr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the <i>j</i> -th column of the solution matrix <i>x</i>). If <i>xtrue</i> is the true solution corresponding to $x(j)$, <i>ferr(j)</i> is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes $x(j)$ an exact solution.
<i>equed</i>	If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>info</i>	INTEGER. If <i>info</i> =0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

If $info = i$, and $i \leq n$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n + 1$, then U is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ppsvx` interface are as follows:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>x</code>	Holds the matrix X of size $(n, nrhs)$.
<code>afp</code>	Holds the matrix AF of size $(n*(n+1)/2)$.
<code>s</code>	Holds the vector of length n . Default value for each element is $s(i) = 1.0_WP$.
<code>ferr</code>	Holds the vector of length $(nrhs)$.
<code>berr</code>	Holds the vector of length $(nrhs)$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>fact</code>	Must be 'N', 'E', or 'F'. The default value is 'N'. If <code>fact = 'F'</code> , then <code>af</code> must be present; otherwise, an error is returned.
<code>equed</code>	Must be 'N' or 'Y'. The default value is 'N'.

?pbsv

Computes the solution to the system of linear equations with a symmetric or Hermitian positive-definite band matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call spbsv( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call dpbsv( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call cpbsv( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
call zpbsv( uplo, n, kd, nrhs, ab, ldab, b, ldb, info )
```

Fortran 95:

```
call pbsv( ab, b [,uplo] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the real or complex system of linear equations $A * X = B$, where A is an n -by- n symmetric/Hermitian positive definite band matrix, the columns of matrix B are individual right-hand sides, and the columns of x are the corresponding solutions.

The Cholesky decomposition is used to factor A as

$A = U^T * U$ (real flavors) and $A = U^H * U$ (complex flavors), if `uplo = 'U'`

or $A = L * L^T$ (real flavors) and $A = L * L^H$ (complex flavors), if `uplo = 'L'`,

where U is an upper triangular band matrix and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A . The factored form of A is then used to solve the system of equations $A * X = B$.

Input Parameters

`uplo` CHARACTER*1. Must be 'U' or 'L'.
Indicates whether the upper or lower triangular part of A is stored:
If `uplo = 'U'`, the upper triangle of A is stored.

	If $uplo = 'L'$, the lower triangle of A is stored.
n	INTEGER. The order of matrix A ; $n \geq 0$.
kd	INTEGER. The number of superdiagonals of the matrix A if $uplo = 'U'$, or the number of subdiagonals if $uplo = 'L'$; $kd \geq 0$.
$nrhs$	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
ab, b	REAL for <code>spbsv</code> DOUBLE PRECISION for <code>dpbsv</code> COMPLEX for <code>cpbsv</code> DOUBLE COMPLEX for <code>zpbsv</code> . Arrays: $ab(ldab, *)$, $b(l db, *)$. The array ab contains the upper or the lower triangular part of the matrix A (as specified by $uplo$) in <i>band storage</i> (see Matrix Storage Schemes). The second dimension of ab must be at least $\max(1, n)$. The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.
$ldab$	INTEGER. The first dimension of the array ab ; $ldab \geq kd + 1$.
ldb	INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

ab	The upper or lower triangular part of A (in band storage) is overwritten by the Cholesky factor U or L , as specified by $uplo$, in the same storage format as A .
b	Overwritten by the solution matrix x .
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution has not been computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbsv` interface are as follows:

<code>ab</code>	Holds the array A of size $(kd+1, n)$.
<code>b</code>	Holds the matrix B of size $(n, nrhs)$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

?pbsvx

Uses the Cholesky factorization to compute the solution to the system of linear equations with a symmetric (Hermitian) positive-definite band matrix A , and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call spbsvx( fact, uplo, n, kd, nrhs, ab, ldab, afb, ldafb, equed, s, b, ldb,
x, ldx, rcond, ferr, berr, work, iwork, info )

call dpbsvx( fact, uplo, n, kd, nrhs, ab, ldab, afb, ldafb, equed, s, b, ldb,
x, ldx, rcond, ferr, berr, work, iwork, info )

call cpbsvx( fact, uplo, n, kd, nrhs, ab, ldab, afb, ldafb, equed, s, b, ldb,
x, ldx, rcond, ferr, berr, work, rwork, info )

call zpbsvx( fact, uplo, n, kd, nrhs, ab, ldab, afb, ldafb, equed, s, b, ldb,
x, ldx, rcond, ferr, berr, work, rwork, info )
```

Fortran 95:

```
call pbsvx( ab, b, x [,uplo] [,afb] [,fact] [,equed] [,s] [,ferr] [,berr]
[,rcond] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine uses the Cholesky factorization $A=U^T*U$ (real flavors) / $A=U^H*U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where A is a n -by- n symmetric or Hermitian positive definite band matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?pbsvx` performs the following steps:

1. If `fact = 'E'`, real scaling factors s are computed to equilibrate the system:

$$diag(s)*A*diag(s)*inv(diag(s))*X = diag(s)*B.$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(s)*A*diag(s)$ and B by $diag(s)*B$.

2. If `fact = 'N'` or `'E'`, the Cholesky decomposition is used to factor the matrix A (after equilibration if `fact = 'E'`) as

$$A = U^T*U \text{ (real), } A = U^H*U \text{ (complex), if } uplo = 'U',$$

$$\text{or } A = L*L^T \text{ (real), } A = L*L^H \text{ (complex), if } uplo = 'L',$$

where U is an upper triangular band matrix and L is a lower triangular band matrix.

3. If the leading i -by- i principal minor is not positive definite, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n+1` is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $diag(s)$ so that it solves the original system before equilibration.

Input Parameters

`fact` CHARACTER*1. Must be 'F', 'N', or 'E'.
Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If *fact* = 'F': on entry, *afb* contains the factored form of *A*. If *equed* = 'Y', the matrix *A* has been equilibrated with scaling factors given by *s*.
ab and *afb* will not be modified.
 If *fact* = 'N', the matrix *A* will be copied to *afb* and factored.
 If *fact* = 'E', the matrix *A* will be equilibrated if necessary, then copied to *afb* and factored.

uplo CHARACTER*1. Must be 'U' or 'L'.
 Indicates whether the upper or lower triangular part of *A* is stored:
 If *uplo* = 'U', the upper triangle of *A* is stored.
 If *uplo* = 'L', the lower triangle of *A* is stored.

n INTEGER. The order of matrix *A*; $n \geq 0$.

kd INTEGER. The number of superdiagonals or subdiagonals in the matrix *A*; $kd \geq 0$.

nrhs INTEGER. The number of right-hand sides, the number of columns in *B*; $nrhs \geq 0$.

ab, afb, b, work REAL for *spbsvx*
 DOUBLE PRECISION for *dpbsvx*
 COMPLEX for *cpbsvx*
 DOUBLE COMPLEX for *zpbsvx*.
 Arrays: *ab(ldab,*)*, *afb(ldab,*)*, *b(ldb,*)*, *work(*)*.
 The array *ab* contains the upper or lower triangle of the matrix *A* in *band storage* (see [Matrix Storage Schemes](#)).
 If *fact* = 'F' and *equed* = 'Y', then *ab* must contain the equilibrated matrix $diag(s)*A*diag(s)$. The second dimension of *ab* must be at least $\max(1, n)$.
 The array *afb* is an input argument if *fact* = 'F'. It contains the triangular factor *U* or *L* from the Cholesky factorization of the band matrix *A* in the same storage format as *A*. If *equed* = 'Y', then *afb* is the factored form of the equilibrated matrix *A*. The second dimension of *afb* must be at least $\max(1, n)$.
 The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations. The second dimension of *b* must be at least $\max(1, nrhs)$.
work()* is a workspace array.
 The dimension of *work* must be at least $\max(1, 3*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

<i>ldab</i>	INTEGER. The first dimension of <i>ab</i> ; $ldab \geq kd+1$.
<i>ldafb</i>	INTEGER. The first dimension of <i>afb</i> ; $ldafb \geq kd+1$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>equed</i>	CHARACTER*1. Must be 'N' or 'Y'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: if <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N') if <i>equed</i> = 'Y', equilibration was done, that is, <i>A</i> has been replaced by $diag(s)*A*diag(s)$.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i> . This array is an input argument if <i>fact</i> = 'F' only; otherwise it is an output argument. If <i>equed</i> = 'N', <i>s</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive.
<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.
<i>rwork</i>	REAL for <i>cpbsvx</i> DOUBLE PRECISION for <i>zpbsvx</i> . Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

<i>x</i>	REAL for <i>spbsvx</i> DOUBLE PRECISION for <i>dpbsvx</i> COMPLEX for <i>cpbsvx</i> DOUBLE COMPLEX for <i>zpbsvx</i> . Array, DIMENSION (<i>ldx</i> , *).
----------	--

	<p>If $info = 0$ or $info = n+1$, the array x contains the solution matrix x to the <i>original</i> system of equations. Note that if $equed = 'Y'$, A and B are modified on exit, and the solution to the equilibrated system is $inv(diag(s))*X$. The second dimension of x must be at least $\max(1, nrhs)$.</p>
<i>ab</i>	<p>On exit, if $fact = 'E'$ and $equed = 'Y'$, A is overwritten by $diag(s)*A*diag(s)$.</p>
<i>afb</i>	<p>If $fact = 'N'$ or $'E'$, then <i>afb</i> is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A=U^T*U$ or $A=L*L^T$ (real routines), $A=U^H*U$ or $A=L*L^H$ (complex routines) of the original matrix A (if $fact = 'N'$), or of the equilibrated matrix A (if $fact = 'E'$). See the description of <i>ab</i> for the form of the equilibrated matrix.</p>
<i>b</i>	<p>Overwritten by $diag(s)*B$, if $equed = 'Y'$; not changed if $equed = 'N'$.</p>
<i>s</i>	<p>This array is an output argument if $fact \neq 'F'$. See the description of <i>s</i> in <i>Input Arguments</i> section.</p>
<i>rcond</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. An estimate of the reciprocal condition number of the matrix A after equilibration (if done). If <i>rcond</i> is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.</p>
<i>ferr</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j-th column of the solution matrix x). If x_{true} is the true solution corresponding to $x(j)$, $ferr(j)$ is an estimated upper bound for the magnitude of the largest element in $(x(j) - x_{true})$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for <i>rcond</i>, and is almost always a slight overestimate of the true error.</p>
<i>berr</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors.</p>

	Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.
<i>equed</i>	If <i>fact</i> \neq 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , and $i \leq n$, the leading minor of order <i>i</i> (and therefore the matrix A itself) is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed; <i>rcond</i> = 0 is returned. If <i>info</i> = <i>i</i> , and $i = n + 1$, then U is nonsingular, but <i>rcond</i> is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of <i>rcond</i> would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbsvx` interface are as follows:

<i>ab</i>	Holds the array A of size $(kd+1, n)$.
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>afb</i>	Holds the array AF of size $(kd+1, n)$.
<i>s</i>	Holds the vector with the number of elements n . Default value for each element is $s(i) = 1.0_WP$.
<i>ferr</i>	Holds the vector with the number of elements $nrhs$.
<i>berr</i>	Holds the vector with the number of elements $nrhs$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N', 'E', or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then <i>af</i> must be present; otherwise, an error is returned.

equed

Must be 'N' or 'Y'. The default value is 'N'.

?ptsv

Computes the solution to the system of linear equations with a symmetric or Hermitian positive definite tridiagonal matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sptsv( n, nrhs, d, e, b, ldb, info )
call dptsv( n, nrhs, d, e, b, ldb, info )
call cptsv( n, nrhs, d, e, b, ldb, info )
call zptsv( n, nrhs, d, e, b, ldb, info )
```

Fortran 95:

```
call ptsv( d, e, b [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the real or complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric/Hermitian positive-definite tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of x are the corresponding solutions.

A is factored as $A = L^*D^*L^T$ (real flavors) or $A = L^*D^*L^H$ (complex flavors), and the factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>d</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors.

Array, dimension at least $\max(1, n)$. Contains the diagonal elements of the tridiagonal matrix A .

e, b REAL for `sptsv`
 DOUBLE PRECISION for `dptsv`
 COMPLEX for `cptsv`
 DOUBLE COMPLEX for `zptsv`.
 Arrays: $e(n - 1)$, $b(ldb, *)$. The array e contains the $(n - 1)$ subdiagonal elements of A .
 The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

ldb INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

d Overwritten by the n diagonal elements of the diagonal matrix D from the $L^*D^*L^T$ (real)/ $L^*D^*L^H$ (complex) factorization of A .

e Overwritten by the $(n - 1)$ subdiagonal elements of the unit bidiagonal factor L from the factorization of A .

b Overwritten by the solution matrix X .

info INTEGER. If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info = i$, the leading minor of order i (and therefore the matrix A itself) is not positive-definite, and the solution has not been computed.
 The factorization has not been completed unless $i = n$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ptsv` interface are as follows:

d Holds the vector of length n .
e Holds the vector of length $(n-1)$.
b Holds the matrix B of size $(n, nrhs)$.

?ptsvx

Uses factorization to compute the solution to the system of linear equations with a symmetric (Hermitian) positive definite tridiagonal matrix A , and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sptsvx( fact, n, nrhs, d, e, df, ef, b, ldb, x, ldx, rcond, ferr, berr,
work, info )
```

```
call dptsvx( fact, n, nrhs, d, e, df, ef, b, ldb, x, ldx, rcond, ferr, berr,
work, info )
```

```
call cptsvx( fact, n, nrhs, d, e, df, ef, b, ldb, x, ldx, rcond, ferr, berr,
work, rwork, info )
```

```
call zptsvx( fact, n, nrhs, d, e, df, ef, b, ldb, x, ldx, rcond, ferr, berr,
work, rwork, info )
```

Fortran 95:

```
call ptsvx( d, e, b, x [,df] [,ef] [,fact] [,ferr] [,berr] [,rcond] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine uses the Cholesky factorization $A = L^*D^*L^T$ (real)/ $A = L^*D^*L^H$ (complex) to compute the solution to a real or complex system of linear equations $A^*X = B$, where A is a n -by- n symmetric or Hermitian positive definite tridiagonal matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?ptsvx performs the following steps:

1. If `fact = 'N'`, the matrix A is factored as $A = L^*D^*L^T$ (real flavors)/ $A = L^*D^*L^H$ (complex flavors), where L is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form $A = U^T*D*U$ (real flavors)/ $A = U^H*D*U$ (complex flavors).

2. If the leading i -by- i principal minor is not positive-definite, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
3. The system of equations is solved for x using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

<i>fact</i>	CHARACTER*1. Must be 'F' or 'N'. Specifies whether or not the factored form of the matrix A is supplied on entry. If <i>fact</i> = 'F': on entry, <i>df</i> and <i>ef</i> contain the factored form of A . Arrays <i>d</i> , <i>e</i> , <i>df</i> , and <i>ef</i> will not be modified. If <i>fact</i> = 'N', the matrix A will be copied to <i>df</i> and <i>ef</i> , and factored.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>d, df, rwork</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Arrays: $d(n)$, $df(n)$, $rwork(n)$. The array <i>d</i> contains the n diagonal elements of the tridiagonal matrix A . The array <i>df</i> is an input argument if <i>fact</i> = 'F' and on entry contains the n diagonal elements of the diagonal matrix D from the $L^*D^*L^T$ (real)/ $L^*D^*L^H$ (complex) factorization of A . The array <i>rwork</i> is a workspace array used for complex flavors only.
<i>e,ef,b,work</i>	REAL for sptsvx DOUBLE PRECISION for dptsvx COMPLEX for cptsvx DOUBLE COMPLEX for zptsvx. Arrays: $e(n-1)$, $ef(n-1)$, $b(l\delta b^*)$, $work(*)$. The array <i>e</i> contains the $(n-1)$ subdiagonal elements of the tridiagonal matrix A .

The array *ef* is an input argument if *fact* = 'F' and on entry contains the $(n - 1)$ subdiagonal elements of the unit bidiagonal factor *L* from the $L^*D^*L^T$ (real)/ $L^*D^*L^H$ (complex) factorization of *A*.

The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

The array *work* is a workspace array. The dimension of *work* must be at least $2*n$ for real flavors, and at least *n* for complex flavors.

ldb INTEGER. The leading dimension of *b*; $ldb \geq \max(1, n)$.

ldx INTEGER. The leading dimension of *x*; $ldx \geq \max(1, n)$.

Output Parameters

x REAL for sptsvx
 DOUBLE PRECISION for dptsvx
 COMPLEX for cptsvx
 DOUBLE COMPLEX for zptsvx.
 Array, DIMENSION (*ldx*, *).
 If *info* = 0 or *info* = *n*+1, the array *x* contains the solution matrix *x* to the system of equations. The second dimension of *x* must be at least $\max(1, nrhs)$.

df, *ef* These arrays are output arguments if *fact* = 'N'. See the description of *df*, *ef* in *Input Arguments* section.

rcond REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 An estimate of the reciprocal condition number of the matrix *A* after equilibration (if done). If *rcond* is less than the machine precision (in particular, if *rcond* = 0), the matrix is singular to working precision. This condition is indicated by a return code of *info* > 0.

ferr REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector *x*(*j*) (the *j*-th column of the solution matrix *x*). If *xtrue* is the true solution corresponding to *x*(*j*), *ferr*(*j*) is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in *x*(*j*). The estimate is as reliable as the estimate for *rcond*, and is almost always a slight overestimate of the true error.

<i>berr</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , and $i \leq n$, the leading minor of order <i>i</i> (and therefore the matrix A itself) is not positive-definite, so the factorization could not be completed, and the solution and error bounds could not be computed; <i>rcond</i> = 0 is returned. If <i>info</i> = <i>i</i> , and $i = n + 1$, then U is nonsingular, but <i>rcond</i> is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of <i>rcond</i> would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ptsvx` interface are as follows:

<i>d</i>	Holds the vector of length n .
<i>e</i>	Holds the vector of length $(n-1)$.
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>df</i>	Holds the vector of length n .
<i>ef</i>	Holds the vector of length $(n-1)$.
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.

?sysv

Computes the solution to the system of linear equations with a real or complex symmetric matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call ssysv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call dsysv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call csysv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call zsysv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
```

Fortran 95:

```
call sysv( a, b [,uplo] [,ipiv] [,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine solves for x the real or complex system of linear equations $A \cdot X = B$, where A is an n -by- n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of x are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U \cdot D \cdot U^T$ or $A = L \cdot D \cdot L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A \cdot X = B$.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <code>uplo</code> = 'U', the upper triangle of A is stored. If <code>uplo</code> = 'L', the lower triangle of A is stored.
<code>n</code>	INTEGER. The order of matrix A ; $n \geq 0$.

<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in <i>B</i> ; $nrhs \geq 0$.
<i>a, b, work</i>	REAL for <i>ssysv</i> DOUBLE PRECISION for <i>dsysv</i> COMPLEX for <i>csysv</i> DOUBLE COMPLEX for <i>zsysv</i> . Arrays: $a(lda, *)$, $b(ldb, *)$, $work(*)$. The array <i>a</i> contains the upper or the lower triangular part of the symmetric matrix <i>A</i> (see <i>uplo</i>). The second dimension of <i>a</i> must be at least $\max(1, n)$. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work</i> is a workspace array, dimension at least $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; $lwork \geq 1$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> below for details and for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	If $info = 0$, <i>a</i> is overwritten by the block-diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> (or <i>L</i>) from the factorization of <i>A</i> as computed by ?sytrf .
<i>b</i>	If $info = 0$, <i>b</i> is overwritten by the solution matrix <i>X</i> .
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of <i>D</i> , as determined by ?sytrf . If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the <i>i</i> -th row and column of <i>A</i> was interchanged with the <i>k</i> -th row and column.

If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

work(1) If $info = 0$, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER. If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sysv* interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector of length n .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For better performance, try using $lwork = n * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sysvx

Uses the diagonal pivoting factorization to compute the solution to the system of linear equations with a real or complex symmetric matrix A , and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call ssysvx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx,
            rcond, ferr, berr, work, lwork, iwork, info )
call dsysvx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx,
            rcond, ferr, berr, work, lwork, iwork, info )
call csysvx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx,
            rcond, ferr, berr, work, lwork, rwork, info )
call zsysvx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx,
            rcond, ferr, berr, work, lwork, rwork, info )
```

Fortran 95:

```
call sysvx( a, b, x [,uplo] [,af] [,ipiv] [,fact] [,ferr] [,berr] [,rcond]
            [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine uses the diagonal pivoting factorization to compute the solution to a real or complex system of linear equations $A \cdot X = B$, where A is a n -by- n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?sysvx` performs the following steps:

1. If `fact = 'N'`, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U^*D^*U^T$ or $A = L^*D^*L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n+1` is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
3. The system of equations is solved for x using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

<code>fact</code>	CHARACTER*1. Must be 'F' or 'N'. Specifies whether or not the factored form of the matrix A has been supplied on entry. If <code>fact = 'F'</code> : on entry, <code>af</code> and <code>ipiv</code> contain the factored form of A . Arrays <code>a</code> , <code>af</code> , and <code>ipiv</code> will not be modified. If <code>fact = 'N'</code> , the matrix A will be copied to <code>af</code> and factored.
<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <code>uplo = 'U'</code> , the upper triangle of A is stored. If <code>uplo = 'L'</code> , the lower triangle of A is stored.
<code>n</code>	INTEGER. The order of matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides, the number of columns in B ; <code>nrhs</code> ≥ 0 .
<code>a, af, b, work</code>	REAL for <code>ssysvx</code> DOUBLE PRECISION for <code>dsysvx</code> COMPLEX for <code>csysvx</code> DOUBLE COMPLEX for <code>zsysvx</code> . Arrays: <code>a(lda,*)</code> , <code>af(ldaf,*)</code> , <code>b(ldb,*)</code> , <code>work(*)</code> .

The array a contains the upper or the lower triangular part of the symmetric matrix A (see $uplo$). The second dimension of a must be at least $\max(1, n)$.

The array af is an input argument if $fact = 'F'$. It contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U**T$ or $A = L*D*L**T$ as computed by `?sytrf`. The second dimension of af must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array, dimension at least $\max(1, lwork)$.

lda	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
$ldaf$	INTEGER. The first dimension of af ; $ldaf \geq \max(1, n)$.
ldb	INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.
$ipiv$	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array $ipiv$ is an input argument if $fact = 'F'$. It contains details of the interchanges and the block structure of D , as determined by <code>?sytrf</code> . If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the i -th row and column of A was interchanged with the k -th row and column. If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column. If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.
ldx	INTEGER. The leading dimension of the output array x ; $ldx \geq \max(1, n)$.
$lwork$	INTEGER. The size of the $work$ array. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code> . See <i>Application Notes</i> below for details and for the suggested value of $lwork$.

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork REAL for *csysvx*;
DOUBLE PRECISION for *zsysvx*.
Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

x REAL for *ssysvx*
DOUBLE PRECISION for *dsysvx*
COMPLEX for *csysvx*
DOUBLE COMPLEX for *zsysvx*.
Array, DIMENSION (*ldx*, *).
If *info* = 0 or *info* = *n*+1, the array *x* contains the solution matrix *x* to the system of equations. The second dimension of *x* must be at least $\max(1, nrhs)$.

af, ipiv These arrays are output arguments if *fact* = 'N'.
See the description of *af, ipiv* in *Input Arguments* section.

rcond REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
An estimate of the reciprocal condition number of the matrix *A*. If *rcond* is less than the machine precision (in particular, if *rcond* = 0), the matrix is singular to working precision. This condition is indicated by a return code of *info* > 0.

ferr REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector *x*(*j*) (the *j*-th column of the solution matrix *x*). If *xtrue* is the true solution corresponding to *x*(*j*), *ferr*(*j*) is an estimated upper bound for the magnitude of the largest element in (*x*(*j*) - *xtrue*) divided by the magnitude of the largest element in *x*(*j*). The estimate is as reliable as the estimate for *rcond*, and is almost always a slight overestimate of the true error.

berr REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.

	Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.
<i>work(1)</i>	If <i>info</i> =0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution and error bounds could not be computed; <i>rcond</i> = 0 is returned. If <i>info</i> = <i>i</i> , and $i = n + 1$, then D is nonsingular, but <i>rcond</i> is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of <i>rcond</i> would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sysvx* interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>af</i>	Holds the matrix AF of size (n, n) .
<i>ipiv</i>	Holds the vector of length n .
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.

Application Notes

For real flavors, *lwork* must be at least $3*n$, and for complex flavors at least $2*n$. For better performance, try using $lwork = n*blocksize$, where *blocksize* is the optimal block size for `?sytrf`.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?sysvxx

Uses extra precise iterative refinement to compute the solution to the system of linear equations with a symmetric indefinite matrix A applying the diagonal pivoting factorization.

Syntax

FORTRAN 77:

```
call ssysvxx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, equed, s, b, ldb,  
x, ldx, rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams,  
params, work, iwork, info )
```

```
call dsysvxx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, equed, s, b, ldb,  
x, ldx, rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams,  
params, work, iwork, info )
```

```
call csysvxx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, equed, s, b, ldb,  
x, ldx, rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams,  
params, work, rwork, info )
```

```
call zsysvxx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, equed, s, b, ldb,
x, ldx, rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams,
params, work, rwork, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine uses the *diagonal pivoting* factorization $A=U^T*U$ (real flavors) / $A=U^H*U$ (complex flavors) or $A=L*L^T$ (real flavors) / $A=L*L^H$ (complex flavors) to compute the solution to a real or complex system of linear equations $A*X = B$, where A is an n -by- n real symmetric/Hermitian matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\epsilon)$, where ϵ is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the `fact` and `equed` options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\epsilon)$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine `?sysvxx` performs the following steps:

1. If `fact = 'E'`, scaling factors are computed to equilibrate the system:

$$\text{diag}(s)*A*\text{diag}(s) * \text{inv}(\text{diag}(s))*X = \text{diag}(s)*B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(s)*A*\text{diag}(s)$ and B by $\text{diag}(s)*B$.

2. If `fact = 'N'` or `'E'`, the LU decomposition is used to factor the matrix A (after equilibration if `fact = 'E'`) as

$$A = U*D*U^T, \text{ if } \text{uplo} = 'U',$$

$$\text{or } A = L*D*L^T, \text{ if } \text{uplo} = 'L',$$

where U or L is a product of permutation and unit upper (lower) triangular matrices, and D is a symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

3. If some $D(i, i) = 0$, so that D is exactly singular, the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A (see the $rcond$ parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for x and compute error bounds.
4. The system of equations is solved for x using the factored form of A .
5. By default, unless `params(la_linrx_itref_i)` is set to zero, the routine applies iterative refinement to get a small error and error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix x is premultiplied by $diag(r)$ so that it solves the original system before equilibration.

Input Parameters

<i>fact</i>	<p>CHARACTER*1. Must be 'F', 'N', or 'E'.</p> <p>Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.</p> <p>If <i>fact</i> = 'F', on entry, <i>af</i> and <i>ipiv</i> contain the factored form of A. If <i>equed</i> is not 'N', the matrix A has been equilibrated with scaling factors given by <i>s</i>. Parameters <i>a</i>, <i>af</i>, and <i>ipiv</i> are not modified.</p> <p>If <i>fact</i> = 'N', the matrix A will be copied to <i>af</i> and factored.</p> <p>If <i>fact</i> = 'E', the matrix A will be equilibrated, if necessary, copied to <i>af</i> and factored.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of A is stored:</p> <p>If <i>uplo</i> = 'U', the upper triangle of A is stored.</p> <p>If <i>uplo</i> = 'L', the lower triangle of A is stored.</p>
<i>n</i>	<p>INTEGER. The number of linear equations; the order of the matrix A; $n \geq 0$.</p>
<i>nrhs</i>	<p>INTEGER. The number of right-hand sides; the number of columns of the matrices B and X; $nrhs \geq 0$.</p>
<i>a, af, b, work</i>	<p>REAL for <code>ssysvxx</code> DOUBLE PRECISION for <code>dsysvxx</code> COMPLEX for <code>csysvxx</code></p>

DOUBLE COMPLEX for `zsysvxx`.

Arrays: `a(lda,*)`, `af(ldaf,*)`, `b ldb,*)`, `work(*)`.

The array `a` contains the symmetric matrix A as specified by `uplo`. If `uplo = 'U'`, the leading n -by- n upper triangular part of `a` contains the upper triangular part of the matrix A and the strictly lower triangular part of `a` is not referenced. If `uplo = 'L'`, the leading n -by- n lower triangular part of `a` contains the lower triangular part of the matrix A and the strictly upper triangular part of `a` is not referenced. The second dimension of `a` must be at least $\max(1, n)$.

The array `af` is an input argument if `fact = 'F'`. It contains the block diagonal matrix D and the multipliers used to obtain the factor U and L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by `?sytrf`. The second dimension of `af` must be at least $\max(1, n)$.

The array `b` contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of `b` must be at least $\max(1, nrhs)$.

`work(*)` is a workspace array. The dimension of `work` must be at least $\max(1, 4*n)$ for real flavors, and at least $\max(1, 2*n)$ for complex flavors.

`lda`

INTEGER. The first dimension of the array `a`; $lda \geq \max(1, n)$.

`ldaf`

INTEGER. The first dimension of the array `af`; $ldaf \geq \max(1, n)$.

`ipiv`

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array `ipiv` is an input argument if `fact = 'F'`. It contains details of the interchanges and the block structure of D as determined by `?sytrf`. If `ipiv(k) > 0`, rows and columns k and `ipiv(k)` were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If `ipiv = 'U'` and `ipiv(k) = ipiv(k-1) < 0`, rows and columns $k-1$ and $-ipiv(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If `ipiv = 'L'` and `ipiv(k) = ipiv(k+1) < 0`, rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

<i>equed</i>	<p>CHARACTER*1. Must be 'N' or 'Y'.</p> <p><i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done:</p> <p>If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N').</p> <p>if <i>equed</i> = 'Y', both row and column equilibration was done, that is, <i>A</i> has been replaced by $diag(s)*A*diag(s)$.</p>
<i>s</i>	<p>REAL for single precision flavors</p> <p>DOUBLE PRECISION for double precision flavors.</p> <p>Array, DIMENSION (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i>. If <i>equed</i> = 'Y', <i>A</i> is multiplied on the left and right by $diag(s)$.</p> <p>This array is an input argument if <i>fact</i> = 'F' only; otherwise it is an output argument.</p> <p>If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive.</p> <p>Each element of <i>s</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.</p>
<i>ldb</i>	<p>INTEGER. The first dimension of the array <i>b</i>; $ldb \geq \max(1, n)$.</p>
<i>ldx</i>	<p>INTEGER. The first dimension of the output array <i>x</i>; $ldx \geq \max(1, n)$.</p>
<i>n_err_bnds</i>	<p>INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in the <i>Output Arguments</i> section below.</p>
<i>nparams</i>	<p>INTEGER. Specifies the number of parameters set in <i>params</i>. If ≤ 0, the <i>params</i> array is never referenced and default values are used.</p>
<i>params</i>	<p>REAL for single precision flavors</p> <p>DOUBLE PRECISION for double precision flavors.</p>

Array, DIMENSION *nparams*. Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with default value used for that parameter. Only positions up to *nparams* are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass *nparams* = 0, which prevents the source code from accessing the *params* argument.

params(*la_linrx_itref_i* = 1) : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors) , 1.0D+0 (for double precision flavors).

=0.0 No refinement is performed and no error bounds are computed.

=1.0 Use the extra-precise refinement algorithm.

(Other values are reserved for future use.)

params(*la_linrx_ithresh_i* = 2) : Maximum number of residual computations allowed for refinement.

Default 10

Aggressive Set to 100 to permit convergence using approximate factorizations or factorizations other than *LU*. If the factorization uses a technique other than Gaussian elimination, the guarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params(*la_linrx_cwise_i* = 3) : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.

Output Parameters

<i>x</i>	<p>REAL for <i>ssysvxx</i> DOUBLE PRECISION for <i>dsysvxx</i> COMPLEX for <i>csysvxx</i> DOUBLE COMPLEX for <i>zsysvxx</i>. Array, DIMENSION (<i>ldx</i>, <i>nrhs</i>). If <i>info</i> = 0, the array <i>x</i> contains the solution <i>n</i>-by-<i>nrhs</i> matrix <i>x</i> to the original system of equations. Note that <i>A</i> and <i>B</i> are modified on exit if <i>equed</i> ≠ 'N', and the solution to the equilibrated system is: $\text{inv}(\text{diag}(s)) * X$.</p>
<i>a</i>	<p>If <i>fact</i> = 'E' and <i>equed</i> = 'Y', overwritten by $\text{diag}(s) * A * \text{diag}(s)$.</p>
<i>af</i>	<p>If <i>fact</i> = 'N', <i>af</i> is an output argument and on exit returns the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> from the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$.</p>
<i>b</i>	<p>If <i>equed</i> = 'N', <i>B</i> is not modified. If <i>equed</i> = 'Y', <i>B</i> is overwritten by $\text{diag}(s) * B$.</p>
<i>s</i>	<p>This array is an output argument if <i>fact</i> ≠ 'F'. Each element of this array is a power of the radix. See the description of <i>s</i> in <i>Input Arguments</i> section.</p>
<i>rcond</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.</p>
<i>rpvgrw</i>	<p>REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Contains the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The <i>max absolute element</i> norm is used. If this is much less than 1, the stability of the <i>LU</i></p>

factorization of the (equilibrated) matrix A could be poor. This also means that the solution x , estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < info \leq n$, this parameter contains the reciprocal pivot growth factor for the leading $info$ columns of A .

berr

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, nrhs)$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.

err_bnds_norm

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION $(nrhs, n_err_bnds)$. For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows:

Normwise relative error in the i -th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in $err_bnds_norm(i, :)$ corresponds to the i -th right-hand side.

The second index in $err_bnds_norm(:, err)$ contains the following three fields:

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true.

err=3 Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for single precision flavors and $\sqrt{n} * \text{dlamch}(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z . Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

err_bnds_comp

REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:
 Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{\text{true}_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each

right-hand side. If componentwise accuracy is not requested ($params(3) = 0.0$), then err_bnds_comp is not accessed. If $n_err_bnds < 3$, then at most the first $(: , n_err_bnds)$ entries are returned.

The first index in $err_bnds_comp(i, :)$ corresponds to the i -th right-hand side.

The second index in $err_bnds_comp(:, err)$ contains the following three fields:

- | | |
|---------|---|
| $err=1$ | "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. |
| $err=2$ | "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors. This error bound should only be trusted if the previous boolean is true. |
| $err=3$ | Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for single precision flavors and $\sqrt{n} * dlamch(\epsilon)$ for double precision flavors to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z . |

Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.

ipiv If *fact* = 'N', *ipiv* is an output argument and on exit contains details of the interchanges and the block structure D , as determined by `ssytrf` for single precision flavors and `dsytrf` for double precision flavors.

equed If *fact* ≠ 'F', then *equed* is an output argument. It specifies the form of equilibration that was done (see the description of *equed* in *Input Arguments* section).

info INTEGER. If *info* = 0, the execution is successful. The solution to every right-hand side is guaranteed. If *info* = -*i*, the *i*-th parameter had an illegal value. If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned. If *info* = $n+j$: The solution corresponding to the *j*-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides *k* with $k > j$ may not be guaranteed as well, but only the first such right-hand side is reported. If a small componentwise error is not requested $\text{params}(3) = 0.0$, then the *j*-th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest *j* such that $\text{err_bnds_norm}(j, 1) = 0.0$ or $\text{err_bnds_comp}(j, 1) = 0.0$. See the definition of $\text{err_bnds_norm}(\ ;, 1)$ and $\text{err_bnds_comp}(\ ;, 1)$. To get information about all of the right-hand sides, check *err_bnds_norm* or *err_bnds_comp*.

?hesv

Computes the solution to the system of linear equations with a Hermitian matrix A and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call chesv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
call zhesv( uplo, n, nrhs, a, lda, ipiv, b, ldb, work, lwork, info )
```

Fortran 95:

```
call hesv( a, b [,uplo] [,ipiv] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the complex system of linear equations $A^*X = B$, where A is an n -by- n symmetric matrix, the columns of matrix B are individual right-hand sides, and the columns of x are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U^*D^*U^H$ or $A = L^*D^*L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If <code>uplo = 'U'</code> , the array <code>a</code> stores the upper triangular part of the matrix A , and A is factored as $U^*D^*U^H$. If <code>uplo = 'L'</code> , the array <code>a</code> stores the lower triangular part of the matrix A , and A is factored as $L^*D^*L^H$.
<code>n</code>	INTEGER. The order of matrix A ; $n \geq 0$.

<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in <i>B</i> ; $nrhs \geq 0$.
<i>a, b, work</i>	COMPLEX for <i>chesv</i> DOUBLE COMPLEX for <i>zhesv</i> . Arrays: <i>a(lda,*)</i> , <i>b(ldb,*)</i> , <i>work(*)</i> . The array <i>a</i> contains the upper or the lower triangular part of the Hermitian matrix <i>A</i> (see <i>uplo</i>). The second dimension of <i>a</i> must be at least $\max(1, n)$. The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work</i> is a workspace array, dimension at least $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array ($lwork \geq 1$). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> below for details and for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	If <i>info</i> = 0, <i>a</i> is overwritten by the block-diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> (or <i>L</i>) from the factorization of <i>A</i> as computed by ?hetrf .
<i>b</i>	If <i>info</i> = 0, <i>b</i> is overwritten by the solution matrix <i>x</i> .
<i>ipiv</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of <i>D</i> , as determined by ?hetrf . If <i>ipiv</i> (<i>i</i>) = <i>k</i> > 0, then <i>d_{ii}</i> is a 1-by-1 diagonal block, and the <i>i</i> -th row and column of <i>A</i> was interchanged with the <i>k</i> -th row and column. If <i>uplo</i> = 'U' and <i>ipiv</i> (<i>i</i>) = <i>ipiv</i> (<i>i</i> -1) = - <i>m</i> < 0, then <i>D</i> has a 2-by-2 block in rows/columns <i>i</i> and <i>i</i> -1, and (<i>i</i> -1)-th row and column of <i>A</i> was interchanged with the <i>m</i> -th row and column.

	If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.
$work(1)$	If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hesv` interface are as follows:

a	Holds the matrix A of size (n, n) .
b	Holds the matrix B of size $(n, nrhs)$.
$ipiv$	Holds the vector of length n .
$uplo$	Must be <code>'U'</code> or <code>'L'</code> . The default value is <code>'U'</code> .

Application Notes

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hesvx

Uses the diagonal pivoting factorization to compute the solution to the complex system of linear equations with a Hermitian matrix A , and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call chesvx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx,  
rcond, ferr, berr, work, lwork, rwork, info )
```

```
call zhesvx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, b, ldb, x, ldx,  
rcond, ferr, berr, work, lwork, rwork, info )
```

Fortran 95:

```
call hesvx( a, b, x [,uplo] [,af] [,ipiv] [,fact] [,ferr] [,berr] [,rcond]  
[,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A*X = B$, where A is an n -by- n Hermitian matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?hesvx performs the following steps:

1. If `fact = 'N'`, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U*D*U^H$ or $A = L*D*L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
3. The system of equations is solved for x using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

<i>fact</i>	CHARACTER*1. Must be 'F' or 'N'. Specifies whether or not the factored form of the matrix A has been supplied on entry. If <i>fact</i> = 'F': on entry, <i>af</i> and <i>ipiv</i> contain the factored form of A . Arrays <i>a</i> , <i>af</i> , and <i>ipiv</i> are not modified. If <i>fact</i> = 'N', the matrix A is copied to <i>af</i> and factored.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored and how A is factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular part of the Hermitian matrix A , and A is factored as $U^*D^*U^H$. If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular part of the Hermitian matrix A ; A is factored as $L^*D^*L^H$.
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>a,af,b,work</i>	COMPLEX for <i>chesvx</i> DOUBLE COMPLEX for <i>zhesvx</i> . Arrays: <i>a(lda,*)</i> , <i>af(ldaf,*)</i> , <i>b(ldb,*)</i> , <i>work(*)</i> . The array <i>a</i> contains the upper or the lower triangular part of the Hermitian matrix A (see <i>uplo</i>). The second dimension of <i>a</i> must be at least $\max(1, n)$. The array <i>af</i> is an input argument if <i>fact</i> = 'F'. It contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^H$ or $A = L^*D^*L^H$ as computed by ?hetrf . The second dimension of <i>af</i> must be at least $\max(1, n)$.

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

$work(*)$ is a workspace array of dimension at least $\max(1, lwork)$.

lda	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
$ldaf$	INTEGER. The first dimension of af ; $ldaf \geq \max(1, n)$.
ldb	INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.
$ipiv$	INTEGER. Array, DIMENSION at least $\max(1, n)$. The array $ipiv$ is an input argument if $fact = 'F'$. It contains details of the interchanges and the block structure of D , as determined by ?hetrf . If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the i -th row and column of A was interchanged with the k -th row and column. If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column. If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.
ldx	INTEGER. The leading dimension of the output array x ; $ldx \geq \max(1, n)$.
$lwork$	INTEGER. The size of the $work$ array. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by $xerbla$. See <i>Application Notes</i> below for details and for the suggested value of $lwork$.
$rwork$	REAL for $chesvx$ DOUBLE PRECISION for $zhesvx$. Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

x	COMPLEX for $chesvx$ DOUBLE COMPLEX for $zhesvx$. Array, DIMENSION ($ldx, *$).
-----	---

	If $info = 0$ or $info = n+1$, the array x contains the solution matrix x to the system of equations. The second dimension of x must be at least $\max(1, nrhs)$.
<i>af, ipiv</i>	These arrays are output arguments if $fact = 'N'$. See the description of <i>af, ipiv</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for <i>chesvx</i> DOUBLE PRECISION for <i>zhesvx</i> . An estimate of the reciprocal condition number of the matrix A . If <i>rcond</i> is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.
<i>ferr</i>	REAL for <i>chesvx</i> DOUBLE PRECISION for <i>zhesvx</i> . Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the j -th column of the solution matrix x). If x_{true} is the true solution corresponding to $x(j)$, $ferr(j)$ is an estimated upper bound for the magnitude of the largest element in $(x(j) - x_{true})$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for $rcond$, and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for <i>chesvx</i> DOUBLE PRECISION for <i>zhesvx</i> . Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of A or B that makes $x(j)$ an exact solution.
<i>work(1)</i>	If $info = 0$, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution and error bounds could not be computed; $rcond = 0$ is returned.

If $info = i$, and $i = n + 1$, then D is nonsingular, but $rcond$ is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of $rcond$ would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hesvx` interface are as follows:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>x</i>	Holds the matrix X of size $(n, nrhs)$.
<i>af</i>	Holds the matrix AF of size (n, n) .
<i>ipiv</i>	Holds the vector of length n .
<i>ferr</i>	Holds the vector of length $(nrhs)$.
<i>berr</i>	Holds the vector of length $(nrhs)$.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.

Application Notes

The value of *lwork* must be at least $2*n$. For better performance, try using $lwork = n*blocksize$, where *blocksize* is the optimal block size for `?hetrf`.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value ($work(1)$) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hesvxx

Uses extra precise iterative refinement to compute the solution to the system of linear equations with a Hermitian indefinite matrix A applying the diagonal pivoting factorization.

Syntax

FORTRAN 77:

```
call chesvxx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, equed, s, b, ldb,  
x, ldx, rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams,  
params, work, rwork, info )
```

```
call zhesvxx( fact, uplo, n, nrhs, a, lda, af, ldaf, ipiv, equed, s, b, ldb,  
x, ldx, rcond, rpvgrw, berr, n_err_bnds, err_bnds_norm, err_bnds_comp, nparams,  
params, work, rwork, info )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface and in `mk1_lapack.h` for C interface.

The routine uses the *diagonal pivoting* factorization to compute the solution to a complex/double complex system of linear equations $A \cdot X = B$, where A is an n -by- n Hermitian matrix, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Both normwise and maximum componentwise error bounds are also provided on request. The routine returns a solution with a small guaranteed error ($O(\text{eps})$, where `eps` is the working machine precision) unless the matrix is very ill-conditioned, in which case a warning is returned. Relevant condition numbers are also calculated and returned.

The routine accepts user-provided factorizations and equilibration factors; see definitions of the *fact* and *equed* options. Solving with refinement and using a factorization from a previous call of the routine also produces a solution with $O(\text{eps})$ errors or warnings but that may not be true for general user-provided factorizations and equilibration factors if they differ from what the routine would itself produce.

The routine `?hesvxx` performs the following steps:

1. If *fact* = 'E', scaling factors are computed to equilibrate the system:

$$\text{diag}(s) * A * \text{diag}(s) * \text{inv}(\text{diag}(s)) * X = \text{diag}(s) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix *A*, but if equilibration is used, *A* is overwritten by $\text{diag}(s) * A * \text{diag}(s)$ and *B* by $\text{diag}(s) * B$.

2. If *fact* = 'N' or 'E', the LU decomposition is used to factor the matrix *A* (after equilibration if *fact* = 'E') as

$$A = U * D * U^T, \text{ if } \text{uplo} = 'U',$$

$$\text{or } A = L * D * L^T, \text{ if } \text{uplo} = 'L',$$

where *U* or *L* is a product of permutation and unit upper (lower) triangular matrices, and *D* is a symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

3. If some $D(i, i) = 0$, so that *D* is exactly singular, the routine returns with *info* = *i*. Otherwise, the factored form of *A* is used to estimate the condition number of the matrix *A* (see the *rcond* parameter). If the reciprocal of the condition number is less than machine precision, the routine still goes on to solve for *x* and compute error bounds.
4. The system of equations is solved for *x* using the factored form of *A*.
5. By default, unless `params(la_linrx_itref_i)` is set to zero, the routine applies iterative refinement to get a small error and error bounds. Refinement calculates the residual to at least twice the working precision.
6. If equilibration was used, the matrix *x* is premultiplied by $\text{diag}(r)$ so that it solves the original system before equilibration.

Input Parameters

fact CHARACTER*1. Must be 'F', 'N', or 'E'.
Specifies whether or not the factored form of the matrix *A* is supplied on entry, and if not, whether the matrix *A* should be equilibrated before it is factored.

If $fact = 'F'$, on entry, af and $ipiv$ contain the factored form of A . If $equed$ is not $'N'$, the matrix A has been equilibrated with scaling factors given by s . Parameters a , af , and $ipiv$ are not modified.

If $fact = 'N'$, the matrix A will be copied to af and factored.

If $fact = 'E'$, the matrix A will be equilibrated, if necessary, copied to af and factored.

$uplo$ CHARACTER*1. Must be $'U'$ or $'L'$.
Indicates whether the upper or lower triangular part of A is stored:
If $uplo = 'U'$, the upper triangle of A is stored.
If $uplo = 'L'$, the lower triangle of A is stored.

n INTEGER. The number of linear equations; the order of the matrix A ; $n \geq 0$.

$nrhs$ INTEGER. The number of right-hand sides; the number of columns of the matrices B and X ; $nrhs \geq 0$.

$a, af, b, work$ COMPLEX for `chesvxx`
DOUBLE COMPLEX for `zhesvxx`.
Arrays: $a(lda, *)$, $af(ldaf, *)$, $b ldb, *)$, $work(*)$.
The array a contains the Hermitian matrix A as specified by $uplo$. If $uplo = 'U'$, the leading n -by- n upper triangular part of a contains the upper triangular part of the matrix A and the strictly lower triangular part of a is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A and the strictly upper triangular part of a is not referenced. The second dimension of a must be at least $\max(1, n)$.
The array af is an input argument if $fact = 'F'$. It contains the block diagonal matrix D and the multipliers used to obtain the factor U and L from the factorization $A = U * D * U^{*T}$ or $A = L * D * L^{*T}$ as computed by `?hetrf`. The second dimension of af must be at least $\max(1, n)$.
The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

	<p><i>work(*)</i> is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 2*n)$.</p>
<i>lda</i>	<p>INTEGER. The first dimension of the array <i>a</i>; $lda \geq \max(1, n)$.</p>
<i>ldaf</i>	<p>INTEGER. The first dimension of the array <i>af</i>; $ldaf \geq \max(1, n)$.</p>
<i>ipiv</i>	<p>INTEGER. Array, DIMENSION at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains details of the interchanges and the block structure of <i>D</i> as determined by ?sytrf. If $ipiv(k) > 0$, rows and columns <i>k</i> and $ipiv(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If $ipiv = 'U'$ and $ipiv(k) = ipiv(k-1) < 0$, rows and columns $k-1$ and $-ipiv(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $ipiv = 'L'$ and $ipiv(k) = ipiv(k+1) < 0$, rows and columns $k+1$ and $-ipiv(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.</p>
<i>equed</i>	<p>CHARACTER*1. Must be 'N' or 'Y'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N'). if <i>equed</i> = 'Y', both row and column equilibration was done, that is, <i>A</i> has been replaced by $diag(s)*A*diag(s)$.</p>
<i>s</i>	<p>REAL for <i>chesvxx</i> DOUBLE PRECISION for <i>zhesvxx</i>. Array, DIMENSION (<i>n</i>). The array <i>s</i> contains the scale factors for <i>A</i>. If <i>equed</i> = 'Y', <i>A</i> is multiplied on the left and right by $diag(s)$. This array is an input argument if <i>fact</i> = 'F' only; otherwise it is an output argument. If <i>fact</i> = 'F' and <i>equed</i> = 'Y', each element of <i>s</i> must be positive. Each element of <i>s</i> should be a power of the radix to ensure a reliable solution and error estimates. Scaling by powers of the radix does not cause rounding errors unless the result</p>

underflows or overflows. Rounding errors during scaling lead to refining with a matrix that is not equivalent to the input matrix, producing error estimates that may not be reliable.

<i>ldb</i>	INTEGER. The first dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ldx</i>	INTEGER. The first dimension of the output array <i>x</i> ; $ldx \geq \max(1, n)$.
<i>n_err_bnds</i>	INTEGER. Number of error bounds to return for each right hand side and each type (normwise or componentwise). See <i>err_bnds_norm</i> and <i>err_bnds_comp</i> descriptions in the <i>Output Arguments</i> section below.
<i>nparams</i>	INTEGER. Specifies the number of parameters set in <i>params</i> . If ≤ 0 , the <i>params</i> array is never referenced and default values are used.
<i>params</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION <i>nparams</i> . Specifies algorithm parameters. If an entry is less than 0.0, that entry will be filled with default value used for that parameter. Only positions up to <i>nparams</i> are accessed; defaults are used for higher-numbered parameters. If defaults are acceptable, you can pass <i>nparams</i> = 0, which prevents the source code from accessing the <i>params</i> argument. <i>params</i> (<i>la_linrx_itref_i</i> = 1) : Whether to perform iterative refinement or not. Default: 1.0 (for single precision flavors), 1.0D+0 (for double precision flavors). =0.0 No refinement is performed and no error bounds are computed. =1.0 Use the extra-precise refinement algorithm. (Other values are reserved for future use.) <i>params</i> (<i>la_linrx_ithresh_i</i> = 2) : Maximum number of residual computations allowed for refinement. Default 10

Aggressive Set to 100 to permit convergence using approximate factorizations or factorizations other than *LU*. If the factorization uses a technique other than Gaussian elimination, the quarantees in *err_bnds_norm* and *err_bnds_comp* may no longer be trustworthy.

params(la_linrx_cwise_i = 3) : Flag determining if the code will attempt to find a solution with a small componentwise relative error in the double-precision algorithm. Positive is true, 0.0 is false. Default: 1.0 (attempt componentwise convergence).

rwork

REAL for *chesvxx*
 DOUBLE PRECISION for *zhesvxx*.
 Workspace array, DIMENSION at least $\max(1, 3*n)$; used in complex flavors only.

Output Parameters

x

COMPLEX for *chesvxx*
 DOUBLE COMPLEX for *zhesvxx*.
 Array, DIMENSION (*ldx*, *nrhs*).
 If *info* = 0, the array *x* contains the solution *n*-by-*nrhs* matrix *x* to the original system of equations. Note that *A* and *B* are modified on exit if *equed* ≠ 'N', and the solution to the equilibrated system is:
 $\text{inv}(\text{diag}(s)) * X$.

a

If *fact* = 'E' and *equed* = 'Y', overwritten by $\text{diag}(s) * A * \text{diag}(s)$.

af

If *fact* = 'N', *af* is an output argument and on exit returns the block diagonal matrix *D* and the multipliers used to obtain the factor *U* or *L* from the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$.

b

If *equed* = 'N', *B* is not modified.
 If *equed* = 'Y', *B* is overwritten by $\text{diag}(s) * B$.

<i>s</i>	This array is an output argument if <i>fact</i> ≠ 'F'. Each element of this array is a power of the radix. See the description of <i>s</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for <i>chesvxx</i> DOUBLE PRECISION for <i>zhesvxx</i> . Reciprocal scaled condition number. An estimate of the reciprocal Skeel condition number of the matrix <i>A</i> after equilibration (if done). If <i>rcond</i> is less than the machine precision, in particular, if <i>rcond</i> = 0, the matrix is singular to working precision. Note that the error may still be small even if this number is very small and the matrix appears ill-conditioned.
<i>rpvgrw</i>	REAL for <i>chesvxx</i> DOUBLE PRECISION for <i>zhesvxx</i> . Contains the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The <i>max absolute element</i> norm is used. If this is much less than 1, the stability of the <i>LU</i> factorization of the (equilibrated) matrix <i>A</i> could be poor. This also means that the solution <i>x</i> , estimated condition numbers, and error bounds could be unreliable. If factorization fails with $0 < \text{info} \leq n$, this parameter contains the reciprocal pivot growth factor for the leading <i>info</i> columns of <i>A</i> .
<i>berr</i>	REAL for <i>chesvxx</i> DOUBLE PRECISION for <i>zhesvxx</i> . Array, DIMENSION at least $\max(1, \text{nrhs})$. Contains the componentwise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes $x(j)$ an exact solution.
<i>err_bnds_norm</i>	REAL for <i>chesvxx</i> DOUBLE PRECISION for <i>zhesvxx</i> . Array, DIMENSION (<i>nrhs</i> , <i>n_err_bnds</i>). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the normwise relative error, which is defined as follows: Normwise relative error in the <i>i</i> -th solution vector

$$\frac{\max_j |X_{true_{ji}} - X_{ji}|}{\max_j |X_{ji}|}$$

The array is indexed by the type of error information as described below. There are currently up to three pieces of information returned.

The first index in `err_bnds_norm(i, :)` corresponds to the *i*-th right-hand side.

The second index in `err_bnds_norm(:, err)` contains the following three fields:

- `err=1` "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for `chesvxx` and $\sqrt{n} * \text{dlamch}(\epsilon)$ for `zh-esvxx`.
- `err=2` "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for `chesvxx` and $\sqrt{n} * \text{dlamch}(\epsilon)$ for `zh-esvxx`. This error bound should only be trusted if the previous boolean is true.
- `err=3` Reciprocal condition number. Estimated normwise reciprocal condition number. Compared with the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for `chesvxx` and $\sqrt{n} * \text{dlamch}(\epsilon)$ for `zh-esvxx` to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix *z*.

Let $z = s * a$, where s scales each row by a power of the radix so all absolute row sums of z are approximately 1.

err_bnds_comp

REAL for *chesvxx*

DOUBLE PRECISION for *zhesvxx*.

Array, DIMENSION (*nrhs*, *n_err_bnds*). For each right-hand side, contains information about various error bounds and condition numbers corresponding to the componentwise relative error, which is defined as follows:

Componentwise relative error in the i -th solution vector:

$$\max_j \frac{|X_{true_{ji}} - X_{ji}|}{|X_{ji}|}$$

The array is indexed by the right-hand side i , on which the componentwise relative error depends, and by the type of error information as described below. There are currently up to three pieces of information returned for each right-hand side. If componentwise accuracy is not requested (*params*(3) = 0.0), then *err_bnds_comp* is not accessed. If *n_err_bnds* < 3, then at most the first ($:$, *n_err_bnds*) entries are returned.

The first index in *err_bnds_comp*(i , $:$) corresponds to the i -th right-hand side.

The second index in *err_bnds_comp*($:$, *err*) contains the following three fields:

err=1 "Trust/don't trust" boolean. Trust the answer if the reciprocal condition number is less than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for *chesvxx* and $\sqrt{n} * \text{dlamch}(\epsilon)$ for *zhesvxx*.

err=2 "Guaranteed" error bound. The estimated forward error, almost certainly within a factor of 10 of the true error so long as the next entry is greater than the threshold $\sqrt{n} * \text{slamch}(\epsilon)$ for *chesvxx* and

	<p>$\sqrt{n} * dlamch(\epsilon)$ for <code>zhesvxx</code>. This error bound should only be trusted if the previous boolean is true.</p>
<code>err=3</code>	<p>Reciprocal condition number. Estimated componentwise reciprocal condition number. Compared with the threshold $\sqrt{n} * slamch(\epsilon)$ for <code>chesvxx</code> and $\sqrt{n} * dlamch(\epsilon)$ for <code>zhesvxx</code> to determine if the error estimate is "guaranteed". These reciprocal condition numbers are $1 / (\text{norm}(1/z, \text{inf}) * \text{norm}(z, \text{inf}))$ for some appropriately scaled matrix z. Let $z = s * (a * \text{diag}(x))$, where x is the solution for the current right-hand side and s scales each row of $a * \text{diag}(x)$ by a power of the radix so all absolute row sums of z are approximately 1.</p>
<code>ipiv</code>	<p>If <code>fact = 'N'</code>, <code>ipiv</code> is an output argument and on exit contains details of the interchanges and the block structure D, as determined by <code>ssytrf</code> for single precision flavors and <code>dsytrf</code> for double precision flavors.</p>
<code>equed</code>	<p>If <code>fact ≠ 'F'</code>, then <code>equed</code> is an output argument. It specifies the form of equilibration that was done (see the description of <code>equed</code> in <i>Input Arguments</i> section).</p>
<code>info</code>	<p>INTEGER. If <code>info = 0</code>, the execution is successful. The solution to every right-hand side is guaranteed. If <code>info = -i</code>, the i-th parameter had an illegal value. If $0 < \text{info} \leq n$: $U(\text{info}, \text{info})$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed; <code>rcond = 0</code> is returned. If <code>info = n+j</code>: The solution corresponding to the j-th right-hand side is not guaranteed. The solutions corresponding to other right-hand sides k with $k > j$ may not be guaranteed as well, but only the first such right-hand</p>

side is reported. If a small componentwise error is not requested $params(3) = 0.0$, then the j -th right-hand side is the first with a normwise error bound that is not guaranteed (the smallest j such that $err_bnds_norm(j,1) = 0.0$ or $err_bnds_comp(j,1) = 0.0$. See the definition of $err_bnds_norm(; ,1)$ and $err_bnds_comp(; ,1)$. To get information about all of the right-hand sides, check err_bnds_norm or err_bnds_comp .

?spsv

Computes the solution to the system of linear equations with a real or complex symmetric matrix A stored in packed format, and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call sspsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call dspsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call cspsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call zspsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
```

Fortran 95:

```
call spsv( ap, b [,uplo] [,ipiv] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the real or complex system of linear equations $Ax = B$, where A is an n -by- n symmetric matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of x are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U^*D^*U^T$ or $A = L^*D^*L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of A is stored: If <i>uplo</i> = 'U', the upper triangle of A is stored. If <i>uplo</i> = 'L', the lower triangle of A is stored.</p>
<i>n</i>	<p>INTEGER. The order of matrix A; $n \geq 0$.</p>
<i>nrhs</i>	<p>INTEGER. The number of right-hand sides, the number of columns in B; $nrhs \geq 0$.</p>
<i>ap, b</i>	<p>REAL for <i>sspsv</i> DOUBLE PRECISION for <i>dspsv</i> COMPLEX for <i>cspsv</i> DOUBLE COMPLEX for <i>zspsv</i>.</p> <p>Arrays: <i>ap</i>(*), <i>b</i>(<i>ldb</i>,*).</p> <p>The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains the factor U or L, as specified by <i>uplo</i>, in <i>packed storage</i> (see Matrix Storage Schemes).</p> <p>The array <i>b</i> contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$.</p>
<i>ldb</i>	<p>INTEGER. The first dimension of <i>b</i>; $ldb \geq \max(1, n)$.</p>

Output Parameters

<i>ap</i>	<p>The block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by <code>?sptrf</code>, stored as a packed triangular matrix in the same storage format as A.</p>
<i>b</i>	<p>If <i>info</i> = 0, <i>b</i> is overwritten by the solution matrix X.</p>
<i>ipiv</i>	<p>INTEGER.</p> <p>Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D, as determined by <code>?sptrf</code>. If <i>ipiv</i>(<i>i</i>) = $k > 0$, then $d_{i,i}$ is a 1-by-1 block, and the <i>i</i>-th row and column of A was interchanged with the <i>k</i>-th row and column.</p>

If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

info

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spsv` interface are as follows:

<i>ap</i>	Holds the array A of size $(n*(n+1))/2$.
<i>b</i>	Holds the matrix B of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector with the number of elements n .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

?spsvx

Uses the diagonal pivoting factorization to compute the solution to the system of linear equations with a real or complex symmetric matrix A stored in packed format, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call sspsvx( fact, uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, rcond, ferr,
berr, work, iwork, info )
```

```
call dspsvx( fact, uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, rcond, ferr,
berr, work, iwork, info )
```

```
call cspsvx( fact, uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, rcond, ferr,  
berr, work, rwork, info )
```

```

berr, work, rwork, info )
```

Fortran 95:

```
call spsvx( ap, b, x [,uplo] [,afp] [,ipiv] [,fact] [,ferr] [,berr] [,rcond]  
[,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine uses the diagonal pivoting factorization to compute the solution to a real or complex system of linear equations $A^*X = B$, where A is a n -by- n symmetric matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of X are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine `?spsvx` performs the following steps:

1. If `fact = 'N'`, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U^*D^*U^T$ or $A = L^*D^*L^T$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with `info = i`. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, `info = n+1` is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

`fact` CHARACTER*1. Must be 'F' or 'N'.
Specifies whether or not the factored form of the matrix A has been supplied on entry.

	<p>If <i>fact</i> = 'F': on entry, <i>afp</i> and <i>ipiv</i> contain the factored form of <i>A</i>. Arrays <i>ap</i>, <i>afp</i>, and <i>ipiv</i> are not modified.</p> <p>If <i>fact</i> = 'N', the matrix <i>A</i> is copied to <i>afp</i> and factored.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of <i>A</i> is stored and how <i>A</i> is factored:</p> <p>If <i>uplo</i> = 'U', the array <i>ap</i> stores the upper triangular part of the symmetric matrix <i>A</i>, and <i>A</i> is factored as $U^*D^*U^T$.</p> <p>If <i>uplo</i> = 'L', the array <i>ap</i> stores the lower triangular part of the symmetric matrix <i>A</i>; <i>A</i> is factored as $L^*D^*L^T$.</p>
<i>n</i>	INTEGER. The order of matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in <i>B</i> ; $nrhs \geq 0$.
<i>ap,afp,b,work</i>	<p>REAL for <i>sspsvx</i> DOUBLE PRECISION for <i>dspsvx</i> COMPLEX for <i>cspsvx</i> DOUBLE COMPLEX for <i>zspsvx</i>.</p> <p>Arrays: <i>ap</i>(*), <i>afp</i>(*), <i>b</i>(<i>ldb</i>,*), <i>work</i>(*).</p> <p>The array <i>ap</i> contains the upper or lower triangle of the symmetric matrix <i>A</i> in <i>packed storage</i> (see Matrix Storage Schemes).</p> <p>The array <i>afp</i> is an input argument if <i>fact</i> = 'F'. It contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> from the factorization $A = U^*D^*U^T$ or $A = L^*D^*L^T$ as computed by ?spturf, in the same storage format as <i>A</i>.</p> <p>The array <i>b</i> contains the matrix <i>B</i> whose columns are the right-hand sides for the systems of equations.</p> <p><i>work</i>(*) is a workspace array.</p> <p>The dimension of arrays <i>ap</i> and <i>afp</i> must be at least $\max(1, n(n+1)/2)$; the second dimension of <i>b</i> must be at least $\max(1, nrhs)$; the dimension of <i>work</i> must be at least $\max(1, 3*n)$ for real flavors and $\max(1, 2*n)$ for complex flavors.</p>
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; $ldb \geq \max(1, n)$.
<i>ipiv</i>	<p>INTEGER.</p> <p>Array, DIMENSION at least $\max(1, n)$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. It contains details of the interchanges and the block structure of <i>D</i>, as determined by ?spturf.</p>

If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the i -th row and column of A was interchanged with the k -th row and column. If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column. If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

ldx INTEGER. The leading dimension of the output array x ; $ldx \geq \max(1, n)$.

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, n)$; used in real flavors only.

rwork REAL for `cspsvx`
DOUBLE PRECISION for `zspsvx`.
Workspace array, DIMENSION at least $\max(1, n)$; used in complex flavors only.

Output Parameters

x REAL for `sspsvx`
DOUBLE PRECISION for `dspsvx`
COMPLEX for `cspsvx`
DOUBLE COMPLEX for `zspsvx`.
Array, DIMENSION ($ldx, *$).
If $info = 0$ or $info = n+1$, the array x contains the solution matrix x to the system of equations. The second dimension of x must be at least $\max(1, nrhs)$.

afp, ipiv These arrays are output arguments if $fact = 'N'$. See the description of *afp, ipiv* in *Input Arguments* section.

rcond REAL for single precision flavors.
DOUBLE PRECISION for double precision flavors.
An estimate of the reciprocal condition number of the matrix A . If *rcond* is less than the machine precision (in particular, if $rcond = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.

ferr, berr REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.

Arrays, DIMENSION at least $\max(1, nrhs)$. Contain the component-wise forward and relative backward errors, respectively, for each solution vector.

info

INTEGER. If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix *D* is exactly singular, so the solution and error bounds could not be computed; *rcond* = 0 is returned.

If *info* = *i*, and $i = n + 1$, then *D* is nonsingular, but *rcond* is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of *rcond* would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *spsvx* interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>afp</i>	Holds the array <i>AF</i> of size $(n*(n+1)/2)$.
<i>ipiv</i>	Holds the vector with the number of elements <i>n</i> .
<i>ferr</i>	Holds the vector with the number of elements <i>nrhs</i> .
<i>berr</i>	Holds the vector with the number of elements <i>nrhs</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.

?hpsv

Computes the solution to the system of linear equations with a Hermitian matrix A stored in packed format, and multiple right-hand sides.

Syntax

FORTRAN 77:

```
call chpsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
call zhpsv( uplo, n, nrhs, ap, ipiv, b, ldb, info )
```

Fortran 95:

```
call hpsv( ap, b [,uplo] [,ipiv] [,info] )
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves for x the system of linear equations $A^*X = B$, where A is an n -by- n Hermitian matrix stored in packed format, the columns of matrix B are individual right-hand sides, and the columns of x are the corresponding solutions.

The diagonal pivoting method is used to factor A as $A = U^*D^*U^H$ or $A = L^*D^*L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

The factored form of A is then used to solve the system of equations $A^*X = B$.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of A is stored: If <code>uplo</code> = 'U', the upper triangle of A is stored. If <code>uplo</code> = 'L', the lower triangle of A is stored.
<code>n</code>	INTEGER. The order of matrix A ; $n \geq 0$.
<code>nrhs</code>	INTEGER. The number of right-hand sides; the number of columns in B ; $nrhs \geq 0$.
<code>ap, b</code>	COMPLEX for <code>chpsv</code>

DOUBLE COMPLEX for zhpsv.

Arrays: $ap(*)$, $b(ldb,*)$.

The dimension of ap must be at least $\max(1, n(n+1)/2)$. The array ap contains the factor U or L , as specified by $uplo$, in *packed storage* (see [Matrix Storage Schemes](#)).

The array b contains the matrix B whose columns are the right-hand sides for the systems of equations. The second dimension of b must be at least $\max(1, nrhs)$.

ldb

INTEGER. The first dimension of b ; $ldb \geq \max(1, n)$.

Output Parameters

ap

The block-diagonal matrix D and the multipliers used to obtain the factor U (or L) from the factorization of A as computed by [?hptrf](#), stored as a packed triangular matrix in the same storage format as A .

b

If $info = 0$, b is overwritten by the solution matrix X .

$ipiv$

INTEGER.

Array, DIMENSION at least $\max(1, n)$. Contains details of the interchanges and the block structure of D , as determined by [?hptrf](#).
 If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 block, and the i -th row and column of A was interchanged with the k -th row and column.
 If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i-1$, and $(i-1)$ -th row and column of A was interchanged with the m -th row and column.
 If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then D has a 2-by-2 block in rows/columns i and $i+1$, and $(i+1)$ -th row and column of A was interchanged with the m -th row and column.

$info$

INTEGER. If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, d_{ii} is 0. The factorization has been completed, but D is exactly singular, so the solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpsv` interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>ipiv</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

?hpsvx

Uses the diagonal pivoting factorization to compute the solution to the system of linear equations with a Hermitian matrix A stored in packed format, and provides error bounds on the solution.

Syntax

FORTRAN 77:

```
call chpsvx( fact, uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, rcond, ferr,
berr, work, rwork, info )
```

```
call zhpsvx( fact, uplo, n, nrhs, ap, afp, ipiv, b, ldb, x, ldx, rcond, ferr,
berr, work, rwork, info )
```

Fortran 95:

```
call hpsvx( ap, b, x [,uplo] [,afp] [,ipiv] [,fact] [,ferr] [,berr] [,rcond]
[,info] )
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A*X = B$, where *A* is a *n*-by-*n* Hermitian matrix stored in packed format, the columns of matrix *B* are individual right-hand sides, and the columns of *x* are the corresponding solutions.

Error bounds on the solution and a condition estimate are also provided.

The routine ?hpsvx performs the following steps:

1. If $fact = 'N'$, the diagonal pivoting method is used to factor the matrix A . The form of the factorization is $A = U^*D^*U^H$ or $A = L^*D^*L^H$, where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is a Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.
2. If some $d_{i,i} = 0$, so that D is exactly singular, then the routine returns with $info = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $info = n+1$ is returned as a warning, but the routine still goes on to solve for x and compute error bounds as described below.
3. The system of equations is solved for x using the factored form of A .
4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

Input Parameters

<i>fact</i>	<p>CHARACTER*1. Must be 'F' or 'N'.</p> <p>Specifies whether or not the factored form of the matrix A has been supplied on entry.</p> <p>If $fact = 'F'$: on entry, afp and $ipiv$ contain the factored form of A. Arrays ap, afp, and $ipiv$ are not modified.</p> <p>If $fact = 'N'$, the matrix A is copied to afp and factored.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>Indicates whether the upper or lower triangular part of A is stored and how A is factored:</p> <p>If $uplo = 'U'$, the array ap stores the upper triangular part of the Hermitian matrix A, and A is factored as $U^*D^*U^H$.</p> <p>If $uplo = 'L'$, the array ap stores the lower triangular part of the Hermitian matrix A, and A is factored as $L^*D^*L^H$.</p>
<i>n</i>	INTEGER. The order of matrix A ; $n \geq 0$.
<i>nrhs</i>	INTEGER. The number of right-hand sides, the number of columns in B ; $nrhs \geq 0$.
<i>ap,afp,b,work</i>	<p>COMPLEX for <code>chpsvx</code></p> <p>DOUBLE COMPLEX for <code>zhpsvx</code>.</p> <p>Arrays: $ap(*)$, $afp(*)$, $b(ldb,*)$, $work(*)$.</p> <p>The array ap contains the upper or lower triangle of the Hermitian matrix A in <i>packed storage</i> (see Matrix Storage Schemes).</p>

The array *afp* is an input argument if *fact* = 'F'. It contains the block diagonal matrix *D* and the multipliers used to obtain the factor *U* or *L* from the factorization $A = U * D * U^H$ or $A = L * D * L^H$ as computed by [?hptrf](#), in the same storage format as *A*.

The array *b* contains the matrix *B* whose columns are the right-hand sides for the systems of equations.

work(*) is a workspace array.

The dimension of arrays *ap* and *afp* must be at least $\max(1, n(n+1)/2)$; the second dimension of *b* must be at least $\max(1, nrhs)$; the dimension of *work* must be at least $\max(1, 2 * n)$.

ldb

INTEGER. The first dimension of *b*; $ldb \geq \max(1, n)$.

ipiv

INTEGER.

Array, DIMENSION at least $\max(1, n)$. The array *ipiv* is an input argument if *fact* = 'F'. It contains details of the interchanges and the block structure of *D*, as determined by [?hptrf](#).

If $ipiv(i) = k > 0$, then d_{ii} is a 1-by-1 diagonal block, and the *i*-th row and column of *A* was interchanged with the *k*-th row and column. If $uplo = 'U'$ and $ipiv(i) = ipiv(i-1) = -m < 0$, then *D* has a 2-by-2 block in rows/columns *i* and *i-1*, and (*i-1*)-th row and column of *A* was interchanged with the *m*-th row and column.

If $uplo = 'L'$ and $ipiv(i) = ipiv(i+1) = -m < 0$, then *D* has a 2-by-2 block in rows/columns *i* and *i+1*, and (*i+1*)-th row and column of *A* was interchanged with the *m*-th row and column.

ldx

INTEGER. The leading dimension of the output array *x*; $ldx \geq \max(1, n)$.

rwork

REAL for *chpsvx*

DOUBLE PRECISION for *zhpsvx*.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

x

COMPLEX for *chpsvx*

DOUBLE COMPLEX for *zhpsvx*.

Array, DIMENSION (*ldx*, *).

If *info* = 0 or *info* = *n*+1, the array *x* contains the solution matrix *x* to the system of equations. The second dimension of *x* must be at least $\max(1, nrhs)$.

<i>afp, ipiv</i>	These arrays are output arguments if <i>fact</i> = 'N'. See the description of <i>afp, ipiv</i> in <i>Input Arguments</i> section.
<i>rcond</i>	REAL for <i>chpsvx</i> DOUBLE PRECISION for <i>zhpsvx</i> . An estimate of the reciprocal condition number of the matrix <i>A</i> . If <i>rcond</i> is less than the machine precision (in particular, if <i>rcond</i> = 0), the matrix is singular to working precision. This condition is indicated by a return code of <i>info</i> > 0.
<i>ferr</i>	REAL for <i>chpsvx</i> DOUBLE PRECISION for <i>zhpsvx</i> . Array, DIMENSION at least $\max(1, nrhs)$. Contains the estimated forward error bound for each solution vector $x(j)$ (the <i>j</i> -th column of the solution matrix <i>X</i>). If <i>xtrue</i> is the true solution corresponding to $x(j)$, <i>ferr(j)</i> is an estimated upper bound for the magnitude of the largest element in $(x(j) - xtrue)$ divided by the magnitude of the largest element in $x(j)$. The estimate is as reliable as the estimate for <i>rcond</i> , and is almost always a slight overestimate of the true error.
<i>berr</i>	REAL for <i>chpsvx</i> DOUBLE PRECISION for <i>zhpsvx</i> . Array, DIMENSION at least $\max(1, nrhs)$. Contains the component-wise relative backward error for each solution vector $x(j)$, that is, the smallest relative change in any element of <i>A</i> or <i>B</i> that makes $x(j)$ an exact solution.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , and $i \leq n$, then d_{ii} is exactly zero. The factorization has been completed, but the block diagonal matrix <i>D</i> is exactly singular, so the solution and error bounds could not be computed; <i>rcond</i> = 0 is returned. If <i>info</i> = <i>i</i> , and $i = n + 1$, then <i>D</i> is nonsingular, but <i>rcond</i> is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of <i>rcond</i> would suggest.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or reconstructible arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpsvx` interface are as follows:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>b</i>	Holds the matrix <i>B</i> of size $(n, nrhs)$.
<i>x</i>	Holds the matrix <i>X</i> of size $(n, nrhs)$.
<i>afp</i>	Holds the array <i>AF</i> of size $(n*(n+1)/2)$.
<i>ipiv</i>	Holds the vector with the number of elements <i>n</i> .
<i>ferr</i>	Holds the vector with the number of elements <i>nrhs</i> .
<i>berr</i>	Holds the vector with the number of elements <i>nrhs</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>fact</i>	Must be 'N' or 'F'. The default value is 'N'. If <i>fact</i> = 'F', then both arguments <i>af</i> and <i>ipiv</i> must be present; otherwise, an error is returned.

LAPACK Routines: Least Squares and Eigenvalue Problems

4

This chapter describes the Intel® Math Kernel Library implementation of routines from the LAPACK package that are used for solving linear least squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks.

Sections in this chapter include descriptions of LAPACK [computational routines](#) and [driver routines](#). For full reference on LAPACK routines and related information see [\[LUG\]](#).

Least Squares Problems. A typical *least squares problem* is as follows: given a matrix A and a vector b , find the vector x that minimizes the sum of squares $\sum_i ((Ax)_i - b_i)^2$ or, equivalently, find the vector x that minimizes the 2-norm $\|Ax - b\|_2$.

In the most usual case, A is an m -by- n matrix with $m \geq n$ and $\text{rank}(A) = n$. This problem is also referred to as finding the *least squares solution* to an *overdetermined* system of linear equations (here we have more equations than unknowns). To solve this problem, you can use the QR factorization of the matrix A (see [QR Factorization](#)).

If $m < n$ and $\text{rank}(A) = m$, there exist an infinite number of solutions x which exactly satisfy $Ax = b$, and thus minimize the norm $\|Ax - b\|_2$. In this case it is often useful to find the unique solution that minimizes $\|x\|_2$. This problem is referred to as finding the *minimum-norm solution* to an *underdetermined* system of linear equations (here we have more unknowns than equations). To solve this problem, you can use the LQ factorization of the matrix A (see [LQ Factorization](#)).

In the general case you may have a *rank-deficient least squares problem*, with $\text{rank}(A) < \min(m, n)$: find the *minimum-norm least squares solution* that minimizes both $\|x\|_2$ and $\|Ax - b\|_2^2$. In this case (or when the rank of A is in doubt) you can use the QR factorization with pivoting or *singular value decomposition* (see [Singular Value Decomposition](#)).

Eigenvalue Problems. The eigenvalue problems (from German *eigen* "own") are stated as follows: given a matrix A , find the *eigenvalues* λ and the corresponding *eigenvectors* z that satisfy the equation

$$Az = \lambda z \text{ (right eigenvectors } z)$$

or the equation

$$z^H A = \lambda z^H \text{ (left eigenvectors } z).$$

If A is a real symmetric or complex Hermitian matrix, the above two equations are equivalent, and the problem is called a *symmetric eigenvalue problem*. Routines for solving this type of problems are described in the section [Symmetric Eigenvalue Problems](#).

Routines for solving eigenvalue problems with nonsymmetric or non-Hermitian matrices are described in the section [Nonsymmetric Eigenvalue Problems](#).

The library also includes routines that handle *generalized symmetric-definite eigenvalue problems*: find the eigenvalues λ and the corresponding eigenvectors x that satisfy one of the following equations:

$$Az = \lambda Bz, ABz = \lambda z, \text{ or } BAz = \lambda z,$$

where A is symmetric or Hermitian, and B is symmetric positive-definite or Hermitian positive-definite. Routines for reducing these problems to standard symmetric eigenvalue problems are described in the section [Generalized Symmetric-Definite Eigenvalue Problems](#).

To solve a particular problem, you usually call several computational routines. Sometimes you need to combine the routines of this chapter with other LAPACK routines described in Chapter 3 as well as with BLAS routines described in Chapter 2.

For example, to solve a set of least squares problems minimizing $\|Ax - b\|^2$ for all columns b of a given matrix B (where A and B are real matrices), you can call `?gqrf` to form the factorization $A = QR$, then call `?ormqr` to compute $C = Q^H B$ and finally call the BLAS routine `?trsm` to solve for X the system of equations $RX = C$.

Another way is to call an appropriate driver routine that performs several tasks in one call. For example, to solve the least squares problem the driver routine `?gels` can be used.

WARNING. LAPACK routines require that input matrices do not contain `INF` or `NaN` values. When input data is inappropriate for LAPACK, problems may arise, including possible hangs.

Starting from release 8.0, Intel MKL along with FORTRAN 77 interface to LAPACK computational and driver routines supports also Fortran 95 interface which uses simplified routine calls with shorter argument lists. The calling sequence for Fortran 95 interface is given in the syntax section of the routine description immediately after FORTRAN 77 calls.

Routine Naming Conventions

For each routine in this chapter, when calling it from the FORTRAN 77 program you can use the LAPACK name.

LAPACK names have the structure `xyyzzz`, which is described below.

The initial letter `x` indicates the data type:

<code>s</code>	real, single precision
<code>c</code>	complex, single precision
<code>d</code>	real, double precision
<code>z</code>	complex, double precision

The second and third letters *yy* indicate the matrix type and storage scheme:

<i>bd</i>	bidiagonal matrix
<i>ge</i>	general matrix
<i>gb</i>	general band matrix
<i>hs</i>	upper Hessenberg matrix
<i>or</i>	(real) orthogonal matrix
<i>op</i>	(real) orthogonal matrix (packed storage)
<i>un</i>	(complex) unitary matrix
<i>up</i>	(complex) unitary matrix (packed storage)
<i>pt</i>	symmetric or Hermitian positive-definite tridiagonal matrix
<i>sy</i>	symmetric matrix
<i>sp</i>	symmetric matrix (packed storage)
<i>sb</i>	(real) symmetric band matrix
<i>st</i>	(real) symmetric tridiagonal matrix
<i>he</i>	Hermitian matrix
<i>hp</i>	Hermitian matrix (packed storage)
<i>hb</i>	(complex) Hermitian band matrix
<i>tr</i>	triangular or quasi-triangular matrix.

The last three letters *zzz* indicate the computation performed, for example:

<i>qrf</i>	form the <i>QR</i> factorization
<i>lqf</i>	form the <i>LQ</i> factorization.

Thus, the routine *sgeqrf* forms the *QR* factorization of general real matrices in single precision; the corresponding routine for complex matrices is *cgeqrf*.

Names of the LAPACK computational and driver routines for Fortran 95 interface in Intel MKL are the same as FORTRAN 77 names but without the first letter that indicates the data type. For example, the name of the routine that forms the *QR* factorization of general real matrices in Fortran 95 interface is *geqrf*. Handling of different data types is done through defining a specific internal parameter referring to a module block with named constants for single and double precision.

For details on the design of Fortran 95 interface for LAPACK computational and driver routines in Intel MKL and for the general information on how the optional arguments are reconstructed, see [Fortran 95 Interface Conventions](#) in chapter 3 .

Matrix Storage Schemes

LAPACK routines use the following matrix storage schemes:

- *Full storage*: a matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.
- *Packed storage* scheme allows you to store symmetric, Hermitian, or triangular matrices more compactly: the upper or lower triangle of the matrix is packed by columns in a one-dimensional array.
- *Band storage*: an m -by- n band matrix with k_l sub-diagonals and k_u super-diagonals is stored compactly in a two-dimensional array ab with k_l+k_u+1 rows and n columns. Columns of the matrix are stored in the corresponding columns of the array, and *diagonals* of the matrix are stored in rows of the array.

In Chapters 3 and 4, arrays that hold matrices in packed storage have names ending in p ; arrays with matrices in band storage have names ending in b . For more information on matrix storage schemes, see “[Matrix Arguments](#)” in Appendix B.

Mathematical Notation

In addition to the mathematical notation used in previous chapters, descriptions of routines in this chapter use the following notation:

λ_i	<i>Eigenvalues</i> of the matrix A (for the definition of eigenvalues, see Eigenvalue Problems).
σ_i	<i>Singular values</i> of the matrix A . They are equal to square roots of the eigenvalues of $A^H A$. (For more information, see Singular Value Decomposition).
$\ x\ _2$	The <i>2-norm</i> of the vector x : $\ x\ _2 = (\sum_i x_i ^2)^{1/2} = \ x\ _E$.
$\ A\ _2$	The <i>2-norm</i> (or <i>spectral norm</i>) of the matrix A . $\ A\ _2 = \max_i \sigma_i$, $\ A\ _2^2 = \max_{ x =1} (Ax \cdot Ax)$.
$\ A\ _E$	The <i>Euclidean norm</i> of the matrix A : $\ A\ _E^2 = \sum_i \sum_j a_{ij} ^2$ (for vectors, the Euclidean norm and the 2-norm are equal: $\ x\ _E = \ x\ _2$).
$\alpha(x, y)$	The <i>acute angle between vectors</i> x and y : $\cos \alpha(x, y) = x \cdot y / (\ x\ _2 \ y\ _2)$.

Computational Routines

In the sections that follow, the descriptions of LAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

[Orthogonal Factorizations](#)

[Singular Value Decomposition](#)

[Symmetric Eigenvalue Problems](#)

[Generalized Symmetric-Definite Eigenvalue Problems](#)

[Nonsymmetric Eigenvalue Problems](#)

[Generalized Nonsymmetric Eigenvalue Problems](#)

[Generalized Singular Value Decomposition](#)

See also the respective [driver routines](#).

Orthogonal Factorizations

This section describes the LAPACK routines for the QR (RQ) and LQ (QL) factorization of matrices. Routines for the RZ factorization as well as for generalized QR and RQ factorizations are also included.

QR Factorization. Assume that A is an m -by- n matrix to be factored.

If $m \geq n$, the QR factorization is given by

$$A = Q \begin{pmatrix} R \\ 0 \end{pmatrix} = (Q_1, Q_2) \begin{pmatrix} R \\ 0 \end{pmatrix}$$

where R is an n -by- n upper triangular matrix with real diagonal elements, and Q is an m -by- m orthogonal (or unitary) matrix.

You can use the QR factorization for solving the following least squares problem: minimize $\|Ax - b\|^2$ where A is a full-rank m -by- n matrix ($m \geq n$). After factoring the matrix, compute the solution x by solving $Rx = (Q_1)^T b$.

If $m < n$, the QR factorization is given by

$$A = QR = Q(R_1 R_2)$$

where R is trapezoidal, R_1 is upper triangular and R_2 is rectangular.

The LAPACK routines do not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

LQ Factorization LQ factorization of an m -by- n matrix A is as follows. If $m \leq n$,

$$A = (L, 0) Q = (L, 0) \begin{pmatrix} Q_1 \\ Q_2 \end{pmatrix} = (LQ1)$$

where L is an m -by- m lower triangular matrix with real diagonal elements, and Q is an n -by- n orthogonal (or unitary) matrix.

If $m > n$, the LQ factorization is

$$A = \begin{pmatrix} L_1 \\ L_2 \end{pmatrix} Q$$

where L_1 is an n -by- n lower triangular matrix, L_2 is rectangular, and Q is an n -by- n orthogonal (or unitary) matrix.

You can use the LQ factorization to find the minimum-norm solution of an underdetermined system of linear equations $Ax = b$ where A is an m -by- n matrix of rank m ($m < n$). After factoring the matrix, compute the solution vector x as follows: solve $Ly = b$ for y , and then compute $x = (Q_1)^H y$.

[Table 4-1](#) lists LAPACK routines (FORTRAN 77 interface) that perform orthogonal factorization of matrices. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

pair of matrices, generalized RQ factorization	?ggrqf			

[?geqrf](#)

Computes the QR factorization of a general m -by- n matrix.

Syntax

FORTRAN 77:

```
call sgeqrf(m, n, a, lda, tau, work, lwork, info)
call dgeqrf(m, n, a, lda, tau, work, lwork, info)
call cgeqrf(m, n, a, lda, tau, work, lwork, info)
call zgeqrf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call geqrf(a [, tau] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine forms the QR factorization of a general m -by- n matrix A (see [Orthogonal Factorizations](#)). No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

NOTE. This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

<i>m</i>	INTEGER. The number of rows in the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>a, work</i>	REAL for <code>sgeqrf</code> DOUBLE PRECISION for <code>dgeqrf</code> COMPLEX for <code>cgeqrf</code> DOUBLE COMPLEX for <code>zgeqrf</code> . Arrays: $a(lda,*)$ contains the matrix A . The second dimension of a must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of a ; at least $\max(1, m)$.
<i>lwork</i>	INTEGER. The size of the $work$ array ($lwork \geq n$). If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code> . See Application Notes for the suggested value of $lwork$.

Output Parameters

<i>a</i>	Overwritten by the factorization data as follows:
----------	---

	If $m \geq n$, the elements below the diagonal are overwritten by the details of the unitary matrix Q , and the upper triangle is overwritten by the corresponding elements of the upper triangular matrix R .
	If $m < n$, the strictly lower triangular part is overwritten by the details of the unitary matrix Q , and the remaining elements are overwritten by the corresponding elements of the m -by- n upper trapezoidal matrix R .
<i>tau</i>	REAL for <i>sgeqrf</i> DOUBLE PRECISION for <i>dgeqrf</i> COMPLEX for <i>cgeqrf</i> DOUBLE COMPLEX for <i>zgeqrf</i> . Array, DIMENSION at least $\max(1, \min(m, n))$. Contains additional information on the matrix Q .
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = $-i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *geqrf* interface are the following:

<i>a</i>	Holds the matrix A of size (m, n) .
<i>tau</i>	Holds the vector of length $\min(m, n)$

Application Notes

For better performance, try using $lwork = n * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\epsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$\begin{array}{ll} (4/3)n^3 & \text{if } m = n, \\ (2/3)n^2(3m-n) & \text{if } m > n, \\ (2/3)m^2(3n-m) & \text{if } m < n. \end{array}$$

The number of operations for complex flavors is 4 times greater.

To solve a set of least squares problems minimizing $\|A^*x - b\|_2$ for all columns *b* of a given matrix *B*, you can call the following:

<code>?geqrf</code> (this routine)	to factorize $A = QR$;
<code>?ormqr</code>	to compute $C = Q^T * B$ (for real matrices);
<code>?unmqr</code>	to compute $C = Q^H * B$ (for complex matrices);
<code>?trsm</code> (a BLAS routine)	to solve $R * X = C$.

(The columns of the computed *x* are the least squares solution vectors *x*.)

To compute the elements of *Q* explicitly, call

<code>?orgqr</code>	(for real matrices)
<code>?ungqr</code>	(for complex matrices).

?geqpf

Computes the QR factorization of a general m -by- n matrix with pivoting.

Syntax

FORTRAN 77:

```
call sgeqpf(m, n, a, lda, jpvt, tau, work, info)
call dgeqpf(m, n, a, lda, jpvt, tau, work, info)
call cgeqpf(m, n, a, lda, jpvt, tau, work, rwork, info)
call zgeqpf(m, n, a, lda, jpvt, tau, work, rwork, info)
```

Fortran 95:

```
call geqpf(a, jpvt [,tau] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine is deprecated and has been replaced by routine [?geqp3](#).

The routine `?geqpf` forms the QR factorization of a general m -by- n matrix A with column pivoting: $A*P = Q*R$ (see [Orthogonal Factorizations](#)). Here P denotes an n -by- n permutation matrix.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for <code>sgeqpf</code> DOUBLE PRECISION for <code>dgeqpf</code> COMPLEX for <code>cgeqpf</code> DOUBLE COMPLEX for <code>zgeqpf</code> . Arrays: $a(lda,*)$ contains the matrix A . The second dimension of a must be at least $\max(1, n)$.

work (*lwork*) is a workspace array. The size of the *work* array must be at least $\max(1, 3*n)$ for real flavors and at least $\max(1, n)$ for complex flavors.

lda INTEGER. The first dimension of *a*; at least $\max(1, m)$.

jpvt INTEGER. Array, DIMENSION at least $\max(1, n)$.
 On entry, if $jpvt(i) > 0$, the *i*-th column of *A* is moved to the beginning of *A*P* before the computation, and fixed in place during the computation.
 If $jpvt(i) = 0$, the *i*th column of *A* is a free column (that is, it may be interchanged during the computation with any other free column).

rwork REAL for *cgeqpf*
 DOUBLE PRECISION for *zgeqpf*.
 A workspace array, DIMENSION at least $\max(1, 2*n)$.

Output Parameters

a Overwritten by the factorization data as follows:
 If $m \geq n$, the elements below the diagonal are overwritten by the details of the unitary (orthogonal) matrix *Q*, and the upper triangle is overwritten by the corresponding elements of the upper triangular matrix *R*.
 If $m < n$, the strictly lower triangular part is overwritten by the details of the matrix *Q*, and the remaining elements are overwritten by the corresponding elements of the *m*-by-*n* upper trapezoidal matrix *R*.

tau REAL for *sgeqpf*
 DOUBLE PRECISION for *dgeqpf*
 COMPLEX for *cgeqpf*
 DOUBLE COMPLEX for *zgeqpf*.
 Array, DIMENSION at least $\max(1, \min(m, n))$. Contains additional information on the matrix *Q*.

jpvt Overwritten by details of the permutation matrix *P* in the factorization $A*P = Q*R$. More precisely, the columns of *A*P* are the columns of *A* in the following order:
 $jpvt(1), jpvt(2), \dots, jpvt(n)$.

info INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gexppf` interface are the following:

<code>a</code>	Holds the matrix A of size (m, n) .
<code>jpvt</code>	Holds the vector of length n .
<code>tau</code>	Holds the vector of length $\min(m, n)$.

Application Notes

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\epsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$\begin{aligned} (4/3)n^3 & \quad \text{if } m = n, \\ (2/3)n^2(3m-n) & \quad \text{if } m > n, \\ (2/3)m^2(3n-m) & \quad \text{if } m < n. \end{aligned}$$

The number of operations for complex flavors is 4 times greater.

To solve a set of least squares problems minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

<code>?gexppf</code> (this routine)	to factorize $A^*P = Q^*R$;
<code>?ormqr</code>	to compute $C = Q^T * B$ (for real matrices);
<code>?unmqr</code>	to compute $C = Q^H * B$ (for complex matrices);
<code>?trsm</code> (a BLAS routine)	to solve $R^*X = C$.

(The columns of the computed x are the permuted least squares solution vectors x_i ; the output array `jpvt` specifies the permutation order.)

To compute the elements of Q explicitly, call

<code>?orgqr</code>	(for real matrices)
<code>?ungqr</code>	(for complex matrices).

?geqp3

Computes the QR factorization of a general m -by- n matrix with column pivoting using level 3 BLAS.

Syntax

FORTRAN 77:

```
call sgeqp3(m, n, a, lda, jpvt, tau, work, lwork, info)
call dgeqp3(m, n, a, lda, jpvt, tau, work, lwork, info)
call cgeqp3(m, n, a, lda, jpvt, tau, work, lwork, rwork, info)
call zgeqp3(m, n, a, lda, jpvt, tau, work, lwork, rwork, info)
```

Fortran 95:

```
call geqp3(a, jpvt [,tau] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine forms the QR factorization of a general m -by- n matrix A with column pivoting: $A^*P = Q^*R$ (see [Orthogonal Factorizations](#)) using Level 3 BLAS. Here P denotes an n -by- n permutation matrix. Use this routine instead of `?geqpf` for better performance.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for <code>sgeqp3</code> DOUBLE PRECISION for <code>dgeqp3</code> COMPLEX for <code>cgeqp3</code> DOUBLE COMPLEX for <code>zgeqp3</code> .
	Arrays:
a ($lda, *$)	contains the matrix A . The second dimension of a must be at least $\max(1, n)$.

	<i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; must be at least $\max(1, 3*n+1)$ for real flavors, and at least $\max(1, n+1)$ for complex flavors. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> below for details.
<i>jpvt</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. On entry, if <i>jpvt</i> (<i>i</i>) $\neq 0$, the <i>i</i> -th column of <i>A</i> is moved to the beginning of <i>AP</i> before the computation, and fixed in place during the computation. If <i>jpvt</i> (<i>i</i>) = 0, the <i>i</i> -th column of <i>A</i> is a free column (that is, it may be interchanged during the computation with any other free column).
<i>rwork</i>	REAL for cgeqp3 DOUBLE PRECISION for zgeqp3 . A workspace array, DIMENSION at least $\max(1, 2*n)$. Used in complex flavors only.

Output Parameters

<i>a</i>	Overwritten by the factorization data as follows: If $m \geq n$, the elements below the diagonal are overwritten by the details of the unitary (orthogonal) matrix <i>Q</i> , and the upper triangle is overwritten by the corresponding elements of the upper triangular matrix <i>R</i> . If $m < n$, the strictly lower triangular part is overwritten by the details of the matrix <i>Q</i> , and the remaining elements are overwritten by the corresponding elements of the m -by- n upper trapezoidal matrix <i>R</i> .
<i>tau</i>	REAL for sgeqp3 DOUBLE PRECISION for dgeqp3

COMPLEX for `cgeqp3`
 DOUBLE COMPLEX for `zgeqp3`.
 Array, DIMENSION at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors for the matrix Q .

jpvt Overwritten by details of the permutation matrix P in the factorization $A^*P = Q^*R$. More precisely, the columns of AP are the columns of A in the following order:
jpvt(1), *jpvt*(2), ..., *jpvt*(*n*).

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geqp3` interface are the following:

a Holds the matrix A of size (m, n) .
jpvt Holds the vector of length n .
tau Holds the vector of length $\min(m, n)$

Application Notes

To solve a set of least squares problems minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

`?geqp3` (this routine) to factorize $A^*P = Q^*R$;
`?ormqr` to compute $C = Q^T * B$ (for real matrices);
`?unmqr` to compute $C = Q^H * B$ (for complex matrices);
`?trsm` (a BLAS routine) to solve $R^*X = C$.

(The columns of the computed x are the permuted least squares solution vectors x ; the output array *jpvt* specifies the permutation order.)

To compute the elements of Q explicitly, call

`?orgqr` (for real matrices)
`?ungqr` (for complex matrices).

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?orgqr

Generates the real orthogonal matrix Q of the QR factorization formed by ?geqrf.

Syntax

FORTRAN 77:

```
call sorgqr(m, n, k, a, lda, tau, work, lwork, info)
call dorgqr(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgqr(a, tau [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine generates the whole or part of m -by- m orthogonal matrix Q of the QR factorization formed by the routines `sgeqrf/dgeqrf` or `sgeqpf/dgeqpf`. Use this routine after a call to `sgeqrf/dgeqrf` or `sgeqpf/dgeqpf`.

Usually Q is determined from the QR factorization of an m by p matrix A with $m \geq p$. To compute the whole matrix Q , use:

```
call ?orgqr(m, m, p, a, lda, tau, work, lwork, info)
```

To compute the leading p columns of Q (which form an orthonormal basis in the space spanned by the columns of A):

```
call ?orgqr(m, p, p, a, lda, tau, work, lwork, info)
```

To compute the matrix Q^k of the QR factorization of leading k columns of the matrix A :

```
call ?orgqr(m, m, k, a, lda, tau, work, lwork, info)
```

To compute the leading k columns of Q^k (which form an orthonormal basis in the space spanned by leading k columns of the matrix A):

```
call ?orgqr(m, k, k, a, lda, tau, work, lwork, info)
```

Input Parameters

m	INTEGER. The order of the orthogonal matrix Q ($m \geq 0$).
n	INTEGER. The number of columns of Q to be computed ($0 \leq n \leq m$).
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).
$a, \tau, work$	REAL for <code>sorgqr</code> DOUBLE PRECISION for <code>dorgqr</code> Arrays: $a(lda,*)$ and $\tau(*)$ are the arrays returned by <code>sgeqrf / dgeqrf</code> or <code>sgeqpf / dgeqpf</code> . The second dimension of a must be at least $\max(1, n)$. The dimension of τ must be at least $\max(1, k)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
$lwork$	INTEGER. The size of the $work$ array ($lwork \geq n$). If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of $lwork$.

Output Parameters

a	Overwritten by n leading columns of the m -by- m orthogonal matrix Q .
-----	--

work(1) If *info* = 0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orgqr` interface are the following:

a Holds the matrix *A* of size (*m*, *n*).
tau Holds the vector of length (*k*)

Application Notes

For better performance, try using $lwork = n * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed *Q* differs from an exactly orthogonal matrix by a matrix *E* such that

$$\|E\|_2 = O(\epsilon) * \|A\|_2 \text{ where } \epsilon \text{ is the machine precision.}$$

The total number of floating-point operations is approximately $4*m*n*k - 2*(m + n)*k^2 + (4/3)*k^3$.

If $n = k$, the number is approximately $(2/3)*n^2*(3m - n)$.

The complex counterpart of this routine is [?ungqr](#).

?ormqr

Multiplies a real matrix by the orthogonal matrix Q of the QR factorization formed by [?geqrf](#) or [?geqpf](#).

Syntax

FORTRAN 77:

```
call sormqr(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormqr(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormqr(a, tau, c [,side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a real matrix c by Q or Q^T , where Q is the orthogonal matrix Q of the QR factorization formed by the routines [sgeqrf/dgeqrf](#) or [sgeqpf/dgeqpf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q*C$, Q^T*C , $C*Q$, or $C*Q^T$ (overwriting the result on c).

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to c from the left. If <i>side</i> = 'R', Q or Q^T is applied to c from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies c by Q . If <i>trans</i> = 'T', the routine multiplies c by Q^T .

m INTEGER. The number of rows in the matrix *c* ($m \geq 0$).

n INTEGER. The number of columns in *c* ($n \geq 0$).

k INTEGER. The number of elementary reflectors whose product defines the matrix *Q*. Constraints:
 $0 \leq k \leq m$ if *side* = 'L';
 $0 \leq k \leq n$ if *side* = 'R'.

a, tau, c, work REAL for *sgeqrf*
 DOUBLE PRECISION for *dgeqrf*.
 Arrays:
a(lda,)* and *tau(*)* are the arrays returned by *sgeqrf* / *dgeqrf* or *sgeqpf* / *dgeqpf*. The second dimension of *a* must be at least $\max(1, k)$. The dimension of *tau* must be at least $\max(1, k)$.
c(ldc,)* contains the matrix *c*.
 The second dimension of *c* must be at least $\max(1, n)$
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*. Constraints:
 $lda \geq \max(1, m)$ if *side* = 'L';
 $lda \geq \max(1, n)$ if *side* = 'R'.

ldc INTEGER. The first dimension of *c*. Constraint:
 $ldc \geq \max(1, m)$.

lwork INTEGER. The size of the *work* array. Constraints:
 $lwork \geq \max(1, n)$ if *side* = 'L';
 $lwork \geq \max(1, m)$ if *side* = 'R'.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*. See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , Q^T*C , $C*Q$, or $C*Q^T$ (as specified by <i>side</i> and <i>trans</i>).
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormqr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>r</i> , <i>k</i>). <i>r</i> = <i>m</i> if <i>side</i> = 'L'. <i>r</i> = <i>n</i> if <i>side</i> = 'R'.
<i>tau</i>	Holds the vector of length (<i>k</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using *lwork* = *n*blocksize* (if *side* = 'L') or *lwork* = *m*blocksize* (if *side* = 'R') where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1 , the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?unmqr](#).

?ungqr

Generates the complex unitary matrix Q of the QR factorization formed by [?geqrf](#).

Syntax

FORTRAN 77:

```
call cungqr(m, n, k, a, lda, tau, work, lwork, info)
call zungqr(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call ungqr(a, tau [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine generates the whole or part of m -by- m unitary matrix Q of the QR factorization formed by the routines [cgeqrf/zgeqrf](#) or [cgeqpf/zgeqpf](#). Use this routine after a call to [cgeqrf/zgeqrf](#) or [cgeqpf/zgeqpf](#).

Usually Q is determined from the QR factorization of an m by p matrix A with $m \geq p$. To compute the whole matrix Q , use:

```
call ?ungqr(m, m, p, a, lda, tau, work, lwork, info)
```

To compute the leading p columns of Q (which form an orthonormal basis in the space spanned by the columns of A):

```
call ?ungqr(m, p, p, a, lda, tau, work, lwork, info)
```

To compute the matrix Q^k of the QR factorization of the leading k columns of the matrix A :

call `?ungqr(m, m, k, a, lda, tau, work, lwork, info)`

To compute the leading k columns of Q^k (which form an orthonormal basis in the space spanned by the leading k columns of the matrix A):

call `?ungqr(m, k, k, a, lda, tau, work, lwork, info)`

Input Parameters

<i>m</i>	INTEGER. The order of the unitary matrix Q ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of Q to be computed ($0 \leq n \leq m$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq n$).
<i>a, tau, work</i>	COMPLEX for <code>cungqr</code> DOUBLE COMPLEX for <code>zungqr</code> Arrays: <i>a</i> (<i>lda</i> ,*) and <i>tau</i> (*) are the arrays returned by <code>cgeqrf/zgeqrf</code> or <code>cgeqpz/zgeqpz</code> . The second dimension of <i>a</i> must be at least $\max(1, n)$. The dimension of <i>tau</i> must be at least $\max(1, k)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array ($lwork \geq n$). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by n leading columns of the m -by- m unitary matrix Q .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ungqr` interface are the following:

`a` Holds the matrix A of size (m, n) .
`tau` Holds the vector of length (k) .

Application Notes

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1 , then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed Q differs from an exactly unitary matrix by a matrix E such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $16 * m * n * k - 8 * (m + n) * k^2 + (16/3) * k^3$.

If $n = k$, the number is approximately $(8/3) * n^2 * (3m - n)$.

The real counterpart of this routine is `?orgqr`.

?unmqr

Multiplies a complex matrix by the unitary matrix Q of the QR factorization formed by ?geqrf.

Syntax

FORTRAN 77:

```
call cunmqr(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call zunmqr(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmqr(a, tau, c [,side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a rectangular complex matrix C by Q or Q_H , where Q is the unitary matrix Q of the QR factorization formed by the routines `cgeqrf/zgeqrf` or `cgeqpf/zgeqpf`.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (overwriting the result on C).

Input Parameters

<code>side</code>	CHARACTER*1. Must be either 'L' or 'R'. If <code>side</code> = 'L', Q or Q_H is applied to C from the left. If <code>side</code> = 'R', Q or Q_H is applied to C from the right.
<code>trans</code>	CHARACTER*1. Must be either 'N' or 'C'. If <code>trans</code> = 'N', the routine multiplies C by Q . If <code>trans</code> = 'C', the routine multiplies C by Q^H .
<code>m</code>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<code>n</code>	INTEGER. The number of columns in C ($n \geq 0$).
<code>k</code>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if <code>side</code> = 'L';

$0 \leq k \leq n$ if *side* = 'R'.
a, *c*, *tau*, *work* COMPLEX for *cgeqrf*
 DOUBLE COMPLEX for *zgeqrf*.
Arrays:
a(*lda*,*) and *tau*(*) are the arrays returned by *cgeqrf* /
zgeqrf or *cgeqpf* / *zgeqpf*.
 The second dimension of *a* must be at least $\max(1, k)$.
 The dimension of *tau* must be at least $\max(1, k)$.
c(*ldc*,*) contains the matrix *c*.
 The second dimension of *c* must be at least $\max(1, n)$
work is a workspace array, its dimension $\max(1, lwork)$.
lda INTEGER. The first dimension of *a*. Constraints:
 lda $\geq \max(1, m)$ if *side* = 'L';
 lda $\geq \max(1, n)$ if *side* = 'R'.
ldc INTEGER. The first dimension of *c*. Constraint:
 ldc $\geq \max(1, m)$.
lwork INTEGER. The size of the *work* array. Constraints:
 lwork $\geq \max(1, n)$ if *side* = 'L';
 lwork $\geq \max(1, m)$ if *side* = 'R'.
 If *lwork* = -1, then a workspace query is assumed; the
 routine only calculates the optimal size of the *work* array,
 returns this value as the first entry of the *work* array, and
 no error message related to *lwork* is issued by [xerbla](#).
 See *Application notes* for the suggested value of *lwork*.

Output Parameters

c Overwritten by the product Q^*C , $Q^H * C$, C^*Q , or C^*Q^H (as
 specified by *side* and *trans*).
work(1) If *info* = 0, on exit *work*(1) contains the minimum value
 of *lwork* required for optimum performance. Use this *lwork*
 for subsequent runs.
info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmqr` interface are the following:

<code>a</code>	Holds the matrix A of size (r, k) . $r = m$ if <code>side = 'L'</code> . $r = n$ if <code>side = 'R'</code> .
<code>tau</code>	Holds the vector of length (k) .
<code>c</code>	Holds the matrix C of size (m, n) .
<code>side</code>	Must be 'L' or 'R'. The default value is 'L'.
<code>trans</code>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, try using `lwork = n*blocksize` (if `side = 'L'`) or `lwork = m*blocksize` (if `side = 'R'`) where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is `?ormqr`.

?gelqf

Computes the LQ factorization of a general m -by- n matrix.

Syntax

FORTRAN 77:

```
call sgelqf(m, n, a, lda, tau, work, lwork, info)
call dgelqf(m, n, a, lda, tau, work, lwork, info)
call cgelqf(m, n, a, lda, tau, work, lwork, info)
call zgelqf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call gelqf(a [, tau] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine forms the LQ factorization of a general m -by- n matrix A (see [Orthogonal Factorizations](#)). No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

NOTE. This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for <code>sgelqf</code> DOUBLE PRECISION for <code>dgelqf</code> COMPLEX for <code>cgelqf</code>

DOUBLE COMPLEX for `zgelqf`.

Arrays:

`a(lda,*)` contains the matrix `A`.

The second dimension of `a` must be at least $\max(1, n)$.

`work` is a workspace array, its dimension $\max(1, lwork)$.

`lda`

INTEGER. The first dimension of `a`; at least $\max(1, m)$.

`lwork`

INTEGER. The size of the `work` array; at least $\max(1, m)$.

If `lwork = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `work` array, returns this value as the first entry of the `work` array, and no error message related to `lwork` is issued by `xerbla`.

See *Application Notes* for the suggested value of `lwork`.

Output Parameters

`a`

Overwritten by the factorization data as follows:

If $m \leq n$, the elements above the diagonal are overwritten by the details of the unitary (orthogonal) matrix `Q`, and the lower triangle is overwritten by the corresponding elements of the lower triangular matrix `L`.

If $m > n$, the strictly upper triangular part is overwritten by the details of the matrix `Q`, and the remaining elements are overwritten by the corresponding elements of the m -by- n lower trapezoidal matrix `L`.

`tau`

REAL for `sgelqf`

DOUBLE PRECISION for `dgelqf`

COMPLEX for `cgelqf`

DOUBLE COMPLEX for `zgelqf`.

Array, DIMENSION at least $\max(1, \min(m, n))$.

Contains additional information on the matrix `Q`.

`work(1)`

If `info = 0`, on exit `work(1)` contains the minimum value of `lwork` required for optimum performance. Use this `lwork` for subsequent runs.

`info`

INTEGER.

If `info = 0`, the execution is successful.

If `info = -i`, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gelqf` interface are the following:

<code>a</code>	Holds the matrix A of size (m, n) .
<code>tau</code>	Holds the vector of length $\min(m, n)$.

Application Notes

For better performance, try using `lwork = m*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed factorization is the exact factorization of a matrix $A + E$, where

$$\|E\|_2 = O(\epsilon) \|A\|_2.$$

The approximate number of floating-point operations for real flavors is

$$\begin{aligned} (4/3)n^3 & \quad \text{if } m = n, \\ (2/3)n^2(3m-n) & \quad \text{if } m > n, \\ (2/3)m^2(3n-m) & \quad \text{if } m < n. \end{aligned}$$

The number of operations for complex flavors is 4 times greater.

To find the minimum-norm solution of an underdetermined least squares problem minimizing $\|A^*x - b\|_2$ for all columns b of a given matrix B , you can call the following:

`?gelqf` (this routine) to factorize $A = L^*Q$;

`?trsm` (a BLAS routine) to solve $L^*Y = B$ for Y ;

`?ormlq` to compute $X = (Q_1)^T * Y$ (for real matrices);

`?unmlq` to compute $X = (Q_1)^H * Y$ (for complex matrices).

(The columns of the computed x are the minimum-norm solution vectors x . Here A is an m -by- n matrix with $m < n$; Q_1 denotes the first m columns of Q).

To compute the elements of Q explicitly, call

`?orglq` (for real matrices)

`?unglq` (for complex matrices).

?orglq

Generates the real orthogonal matrix Q of the LQ factorization formed by `?gelqf`.

Syntax

FORTRAN 77:

```
call sorglq(m, n, k, a, lda, tau, work, lwork, info)
```

```
call dorglq(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orglq(a, tau [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine generates the whole or part of n -by- n orthogonal matrix Q of the LQ factorization formed by the routines `sgelqf/gelqf`. Use this routine after a call to `sgelqf/dgelqf`.

Usually Q is determined from the LQ factorization of an p -by- n matrix A with $n \geq p$. To compute the whole matrix Q , use:

```
call ?orglq(n, n, p, a, lda, tau, work, lwork, info)
```

To compute the leading p rows of Q , which form an orthonormal basis in the space spanned by the rows of A , use:

```
call ?orglq(p, n, p, a, lda, tau, work, lwork, info)
```

To compute the matrix Q^k of the LQ factorization of A 's leading k rows, use:

```
call ?orglq(n, n, k, a, lda, tau, work, lwork, info)
```

To compute the leading k rows of Q^k , which form an orthonormal basis in the space spanned by A 's leading k rows, use:

```
call ?orgqr(k, n, k, a, lda, tau, work, lwork, info)
```

Input Parameters

m	INTEGER. The number of rows of Q to be computed ($0 \leq m \leq n$).
n	INTEGER. The order of the orthogonal matrix Q ($n \geq m$).
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq m$).
$a, \tau, work$	REAL for <code>sorglq</code> DOUBLE PRECISION for <code>dorglq</code> Arrays: $a(lda,*)$ and $\tau(*)$ are the arrays returned by <code>sgelqf/dgelqf</code> . The second dimension of a must be at least $\max(1, n)$. The dimension of τ must be at least $\max(1, k)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
$lwork$	INTEGER. The size of the $work$ array; at least $\max(1, m)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of $lwork$.

Output Parameters

a	Overwritten by m leading rows of the n -by- n orthogonal matrix Q .
-----	---

work(1) If *info* = 0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orglq` interface are the following:

a Holds the matrix *A* of size (*m*,*n*).

tau Holds the vector of length (*k*).

Application Notes

For better performance, try using $lwork = m * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed *Q* differs from an exactly orthogonal matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $4*m*n*k - 2*(m + n)*k^2 + (4/3)*k^3$.

If $m = k$, the number is approximately $(2/3)*m^2*(3n - m)$.

The complex counterpart of this routine is [?unglq](#).

?ormlq

Multiplies a real matrix by the orthogonal matrix Q of the LQ factorization formed by ?gelqf.

Syntax

FORTRAN 77:

```
call sormlq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormlq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormlq(a, tau, c [,side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the orthogonal matrix Q of the LQ factorization formed by the routine [sgelqf/dgelqf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q*C$, Q^T*C , $C*Q$, or $C*Q^T$ (overwriting the result on C).

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to C from the left. If <i>side</i> = 'R', Q or Q^T is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies C by Q . If <i>trans</i> = 'T', the routine multiplies C by Q^T .
<i>m</i>	INTEGER. The number of rows in the matrix C ($m \geq 0$).

<i>n</i>	INTEGER. The number of columns in <i>c</i> ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix <i>Q</i> . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'.
<i>a</i> , <i>c</i> , <i>tau</i> , <i>work</i>	REAL for <code>sormlq</code> DOUBLE PRECISION for <code>dormlq</code> . Arrays: <i>a</i> (<i>lda</i> ,*) and <i>tau</i> (*) are arrays returned by <code>?gelqf</code> . The second dimension of <i>a</i> must be: at least $\max(1, m)$ if <i>side</i> = 'L'; at least $\max(1, n)$ if <i>side</i> = 'R'. The dimension of <i>tau</i> must be at least $\max(1, k)$. <i>c</i> (<i>ldc</i> ,*) contains the matrix <i>c</i> . The second dimension of <i>c</i> must be at least $\max(1, n)$ <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, k)$.
<i>ldc</i>	INTEGER. The first dimension of <i>c</i> ; $ldc \geq \max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints: $lwork \geq \max(1, n)$ if <i>side</i> = 'L'; $lwork \geq \max(1, m)$ if <i>side</i> = 'R'. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>c</i>	Overwritten by the product $Q^T C$, $Q^T * C$, $C * Q$, or $C * Q^T$ (as specified by <i>side</i> and <i>trans</i>).
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormlq` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>k</i> , <i>m</i>).
<i>tau</i>	Holds the vector of length (<i>k</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n * blocksize$ (if *side* = 'L') or $lwork = m * blocksize$ (if *side* = 'R') where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork*= -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork*= -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is `?unmlq`.

?unglq

Generates the complex unitary matrix Q of the LQ factorization formed by ?gelqf.

Syntax

FORTRAN 77:

```
call cunglq(m, n, k, a, lda, tau, work, lwork, info)
call zunglq(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call unglq(a, tau [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine generates the whole or part of n -by- n unitary matrix Q of the LQ factorization formed by the routines `cgelqf/zgelqf`. Use this routine after a call to `cgelqf/zgelqf`.

Usually Q is determined from the LQ factorization of an p -by- n matrix A with $n < p$. To compute the whole matrix Q , use:

```
call ?unglq(n, n, p, a, lda, tau, work, lwork, info)
```

To compute the leading p rows of Q , which form an orthonormal basis in the space spanned by the rows of A , use:

```
call ?unglq(p, n, p, a, lda, tau, work, lwork, info)
```

To compute the matrix Q^k of the LQ factorization of the leading k rows of the matrix A , use:

```
call ?unglq(n, n, k, a, lda, tau, work, lwork, info)
```

To compute the leading k rows of Q^k , which form an orthonormal basis in the space spanned by the leading k rows of the matrix A , use:

```
call ?ungqr(k, n, k, a, lda, tau, work, lwork, info)
```

Input Parameters

m INTEGER. The number of rows of Q to be computed ($0 \leq m \leq n$).

<i>n</i>	INTEGER. The order of the unitary matrix Q ($n \geq m$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($0 \leq k \leq m$).
<i>a</i> , <i>tau</i> , <i>work</i>	COMPLEX for <code>cunglq</code> DOUBLE COMPLEX for <code>zunglq</code> Arrays: <i>a</i> (<i>lda</i> ,*) and <i>tau</i> (*) are the arrays returned by <code>sgelqf/dgelqf</code> . The second dimension of <i>a</i> must be at least $\max(1, n)$. The dimension of <i>tau</i> must be at least $\max(1, k)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; at least $\max(1, m)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by <i>m</i> leading rows of the <i>n</i> -by- <i>n</i> unitary matrix Q .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unglq` interface are the following:

<i>a</i>	Holds the matrix A of size (m, n) .
<i>tau</i>	Holds the vector of length (k) .

Application Notes

For better performance, try using $lwork = m * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed Q differs from an exactly unitary matrix by a matrix E such that $\|E\|_2 = O(\epsilon) * \|A\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $16 * m * n * k - 8 * (m + n) * k^2 + (16/3) * k^3$.

If $m = k$, the number is approximately $(8/3) * m^2 * (3n - m)$.

The real counterpart of this routine is [?orglq](#).

?unmlq

Multiplies a complex matrix by the unitary matrix Q of the LQ factorization formed by ?gelqf.

Syntax

FORTRAN 77:

```
call cunmlq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

```
call zunmlq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmlq(a, tau, c [,side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a real m -by- n matrix C by Q or Q^H , where Q is the unitary matrix Q of the LQ factorization formed by the routine `cgelqf/zgelqf`.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (overwriting the result on C).

Input Parameters

<code>side</code>	CHARACTER*1. Must be either 'L' or 'R'. If <code>side</code> = 'L', Q or Q^H is applied to C from the left. If <code>side</code> = 'R', Q or Q^H is applied to C from the right.
<code>trans</code>	CHARACTER*1. Must be either 'N' or 'C'. If <code>trans</code> = 'N', the routine multiplies C by Q . If <code>trans</code> = 'C', the routine multiplies C by Q^H .
<code>m</code>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<code>n</code>	INTEGER. The number of columns in C ($n \geq 0$).
<code>k</code>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if <code>side</code> = 'L'; $0 \leq k \leq n$ if <code>side</code> = 'R'.
<code>a, c, tau, work</code>	COMPLEX for <code>cunmlq</code> DOUBLE COMPLEX for <code>zunmlq</code> . Arrays: <code>a(lda,*)</code> and <code>tau(*)</code> are arrays returned by <code>?gelqf</code> . The second dimension of <code>a</code> must be: at least $\max(1, m)$ if <code>side</code> = 'L'; at least $\max(1, n)$ if <code>side</code> = 'R'. The dimension of <code>tau</code> must be at least $\max(1, k)$. <code>c ldc,*)</code> contains the matrix C . The second dimension of <code>c</code> must be at least $\max(1, n)$

work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, k)$.

ldc INTEGER. The first dimension of *c*; $ldc \geq \max(1, m)$.

lwork INTEGER. The size of the *work* array. Constraints:
 $lwork \geq \max(1, n)$ if *side* = 'L';
 $lwork \geq \max(1, m)$ if *side* = 'R'.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

Output Parameters

c Overwritten by the product Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (as specified by *side* and *trans*).

work(1) If *info* = 0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmlq` interface are the following:

a Holds the matrix *A* of size (*k*,*m*).

tau Holds the vector of length (*k*).

c Holds the matrix *C* of size (*m*,*n*).

side Must be 'L' or 'R'. The default value is 'L'.

trans Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n * blocksize$ (if $side = 'L'$) or $lwork = m * blocksize$ (if $side = 'R'$) where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [?ormlq](#).

?geqlf

Computes the QL factorization of a general m-by-n matrix.

Syntax

FORTRAN 77:

```
call sgeqlf(m, n, a, lda, tau, work, lwork, info)
```

```
call dgeqlf(m, n, a, lda, tau, work, lwork, info)
```

```
call cgeqlf(m, n, a, lda, tau, work, lwork, info)
```

```
call zgeqlf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call geqlf(a [, tau] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine forms the QL factorization of a general m -by- n matrix A . No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors*. Routines are provided to work with Q in this representation.

NOTE. This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

<i>m</i>	INTEGER. The number of rows in the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).
<i>a, work</i>	REAL for <code>sgeqlf</code> DOUBLE PRECISION for <code>dgeqlf</code> COMPLEX for <code>cgeqlf</code> DOUBLE COMPLEX for <code>zgeqlf</code> . Arrays: $a(lda,*)$ contains the matrix A . The second dimension of a must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of a ; at least $\max(1, m)$.
<i>lwork</i>	INTEGER. The size of the $work$ array; at least $\max(1, n)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of $lwork$.

Output Parameters

<i>a</i>	Overwritten on exit by the factorization data as follows:
----------	---

if $m \geq n$, the lower triangle of the subarray $a(m-n+1:m, 1:n)$ contains the n -by- n lower triangular matrix L ; if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix L ; in both cases, the remaining elements, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors.

tau REAL for sgeqlf
 DOUBLE PRECISION for dgeqlf
 COMPLEX for cgeqlf
 DOUBLE COMPLEX for zgeqlf.
 Array, DIMENSION at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors for the matrix Q .

work(1) If *info* = 0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = $-i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `geqlf` interface are the following:

a Holds the matrix A of size (m, n) .
tau Holds the vector of length $\min(m, n)$.

Application Notes

For better performance, try using $lwork = n * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Related routines include:

<code>?orgql</code>	to generate matrix Q (for real matrices);
<code>?ungql</code>	to generate matrix Q (for complex matrices);
<code>?ormql</code>	to apply matrix Q (for real matrices);
<code>?unmql</code>	to apply matrix Q (for complex matrices).

?orgql

Generates the real matrix Q of the QL factorization formed by ?geqlf.

Syntax

FORTRAN 77:

```
call sorgql(m, n, k, a, lda, tau, work, lwork, info)
call dorgql(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgql(a, tau [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine generates an m -by- n real matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors $H(i)$ of order m : $Q = H(k) * \dots * H(2) * H(1)$ as returned by the routines [sgeqlf/dgeqlf](#). Use this routine after a call to [sgeqlf/dgeqlf](#).

Input Parameters

m INTEGER. The number of rows of the matrix Q ($m \geq 0$).

n INTEGER. The number of columns of the matrix Q ($m \geq n \geq 0$).

k INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).

$a, \tau, work$ REAL for [sorgql](#)
DOUBLE PRECISION for [dorgql](#)
Arrays: $a(lda,*)$, $\tau(*)$.
On entry, the $(n - k + i)$ th column of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by [sgeqlf/dgeqlf](#) in the last k columns of its array argument a ; $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by [sgeqlf/dgeqlf](#);
The second dimension of a must be at least $\max(1, n)$.
The dimension of τ must be at least $\max(1, k)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of a ; at least $\max(1, m)$.

$lwork$ INTEGER. The size of the $work$ array; at least $\max(1, n)$.
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).
See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a Overwritten by the m -by- n matrix Q .

work(1) If *info* = 0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orgql` interface are the following:

a Holds the matrix *A* of size (*m*,*n*).

tau Holds the vector of length (*k*).

Application Notes

For better performance, try using $lwork = n * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?ungql](#).

zungql

Generates the complex matrix Q of the QL factorization formed by `zgeqlf`.

Syntax

FORTRAN 77:

```
call zungql(m, n, k, a, lda, tau, work, lwork, info)
call zungql(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call zungql(a, tau [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine generates an m -by- n complex matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors $H(i)$ of order m : $Q = H(k) * \dots * H(2) * H(1)$ as returned by the routines `cgeqlf/zgeqlf`. Use this routine after a call to `cgeqlf/zgeqlf`.

Input Parameters

m	INTEGER. The number of rows of the matrix Q ($m \geq 0$).
n	INTEGER. The number of columns of the matrix Q ($m \geq n \geq 0$).
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
$a, \tau, work$	COMPLEX for <code>zungql</code> DOUBLE COMPLEX for <code>zungql</code> Arrays: $a(lda,*)$, $\tau(*)$, $work(lwork)$. On entry, the $(n - k + i)$ th column of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <code>cgeqlf/zgeqlf</code> in the last k columns of its array argument a ;

$\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by `cgeqlf/zgeqlf`;
 The second dimension of a must be at least $\max(1, n)$.
 The dimension of τ must be at least $\max(1, k)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda INTEGER. The first dimension of a ; at least $\max(1, m)$.
lwork INTEGER. The size of the $work$ array; at least $\max(1, n)$.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.
 See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a Overwritten by the m -by- n matrix Q .
 $work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ungql` interface are the following:

a Holds the matrix A of size (m, n) .
 τ Holds the vector of length (k) .

Application Notes

For better performance, try using $lwork = n * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [?orgql](#).

?ormql

Multiplies a real matrix by the orthogonal matrix Q of the QL factorization formed by [?geqlf](#).

Syntax

FORTRAN 77:

```
call sormql(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormql(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormql(a, tau, c [,side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a real m -by- n matrix c by q or q^T , where q is the orthogonal matrix Q of the QL factorization formed by the routine [sgeqlf/dgeqlf](#).

Depending on the parameters $side$ and $trans$, the routine [?ormql](#) can form one of the matrix products $Q^T C$, $Q^T * C$, $C * Q$, or $C * Q^T$ (overwriting the result over c).

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^T is applied to c from the left. If <i>side</i> = 'R', Q or Q^T is applied to c from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies c by Q . If <i>trans</i> = 'T', the routine multiplies c by Q^T .
<i>m</i>	INTEGER. The number of rows in the matrix c ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in c ($n \geq 0$).
<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'.
<i>a, tau, c, work</i>	REAL for <code>sormql</code> DOUBLE PRECISION for <code>dormql</code> . Arrays: $a(lda,*)$, $tau(*)$, $c ldc,*)$. On entry, the i th column of a must contain the vector which defines the elementary reflector H_i , for $i = 1, 2, \dots, k$, as returned by <code>sgeqlf/dgeqlf</code> in the last k columns of its array argument a . The second dimension of a must be at least $\max(1, k)$. $tau(i)$ must contain the scalar factor of the elementary reflector H_i , as returned by <code>sgeqlf/dgeqlf</code> . The dimension of tau must be at least $\max(1, k)$. $c(ldc,*)$ contains the m -by- n matrix C . The second dimension of c must be at least $\max(1, n)$ $work$ is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of a ; if <i>side</i> = 'L', $lda \geq \max(1, m)$; if <i>side</i> = 'R', $lda \geq \max(1, n)$.
<i>ldc</i>	INTEGER. The first dimension of c ; $ldc \geq \max(1, m)$.
<i>lwork</i>	INTEGER. The size of the $work$ array. Constraints:

$lwork \geq \max(1, n)$ if $side = 'L'$;

$lwork \geq \max(1, m)$ if $side = 'R'$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , $Q^T * C$, C^*Q , or C^*Q^T (as specified by <i>side</i> and <i>trans</i>).
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormql` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>r</i> , <i>k</i>). $r = m$ if $side = 'L'$. $r = n$ if $side = 'R'$.
<i>tau</i>	Holds the vector of length (<i>k</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n * blocksize$ (if $side = 'L'$) or $lwork = m * blocksize$ (if $side = 'R'$) where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?unmql](#).

?unmql

Multiplies a complex matrix by the unitary matrix Q of the QL factorization formed by [?geqlf](#).

Syntax

FORTRAN 77:

```
call cunmql(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call zunmql(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmql(a, tau, c [,side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a complex m -by- n matrix C by Q or Q^H , where Q is the unitary matrix Q of the QL factorization formed by the routine [cgeqlf/zgeqlf](#).

Depending on the parameters `side` and `trans`, the routine [?unmql](#) can form one of the matrix products Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (overwriting the result over C).

Input Parameters

<i>side</i>	<p>CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to c from the left. If <i>side</i> = 'R', Q or Q^H is applied to c from the right.</p>
<i>trans</i>	<p>CHARACTER*1. Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies c by Q. If <i>trans</i> = 'C', the routine multiplies c by Q^H.</p>
<i>m</i>	INTEGER. The number of rows in the matrix c ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in c ($n \geq 0$).
<i>k</i>	<p>INTEGER. The number of elementary reflectors whose product defines the matrix Q. Constraints: $0 \leq k \leq m$ if <i>side</i> = 'L'; $0 \leq k \leq n$ if <i>side</i> = 'R'.</p>
<i>a, tau, c, work</i>	<p>COMPLEX for <code>cunmql</code> DOUBLE COMPLEX for <code>zunmql</code>. Arrays: $a(lda,*)$, $tau(*)$, $c(ldc,*)$, $work(lwork)$. On entry, the i-th column of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <code>cgeqlf/zgeqlf</code> in the last k columns of its array argument a. The second dimension of a must be at least $\max(1, k)$. $tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by <code>cgeqlf/zgeqlf</code>. The dimension of tau must be at least $\max(1, k)$. $c(ldc,*)$ contains the m-by-n matrix C. The second dimension of c must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	INTEGER. The first dimension of a ; $lda \geq \max(1, n)$.
<i>ldc</i>	INTEGER. The first dimension of c ; $ldc \geq \max(1, m)$.
<i>lwork</i>	<p>INTEGER. The size of the $work$ array. Constraints: $lwork \geq \max(1, n)$ if <i>side</i> = 'L'; $lwork \geq \max(1, m)$ if <i>side</i> = 'R'.</p>

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`. See *Application Notes* for the suggested value of $lwork$.

Output Parameters

c	Overwritten by the product Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (as specified by $side$ and $trans$).
$work(1)$	If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmql` interface are the following:

a	Holds the matrix A of size (r, k) . $r = m$ if $side = 'L'$. $r = n$ if $side = 'R'$.
tau	Holds the vector of length (k) .
c	Holds the matrix C of size (m, n) .
$side$	Must be 'L' or 'R'. The default value is 'L'.
$trans$	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n*blocksize$ (if $side = 'L'$) or $lwork = m*blocksize$ (if $side = 'R'$) where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [?ormql](#).

?gerqf

Computes the RQ factorization of a general m -by- n matrix.

Syntax

FORTRAN 77:

```
call sgerqf(m, n, a, lda, tau, work, lwork, info)
call dgerqf(m, n, a, lda, tau, work, lwork, info)
call cgerqf(m, n, a, lda, tau, work, lwork, info)
call zgerqf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call gerqf(a [, tau] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine forms the RQ factorization of a general m -by- n matrix A . No pivoting is performed.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors. Routines are provided to work with Q in this representation.

NOTE. This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

m INTEGER. The number of rows in the matrix *A* ($m \geq 0$).

n INTEGER. The number of columns in *A* ($n \geq 0$).

a, work REAL for sgerqf
DOUBLE PRECISION for dgerqf
COMPLEX for cgerqf
DOUBLE COMPLEX for zgerqf.
Arrays:
a(lda,)* contains the *m*-by-*n* matrix *A*.
The second dimension of *a* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, m)$.

lwork INTEGER. The size of the *work* array;
 $lwork \geq \max(1, m)$.
If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See [Application Notes](#) for the suggested value of *lwork*.

Output Parameters

a Overwritten on exit by the factorization data as follows:
if $m \leq n$, the upper triangle of the subarray
a(1:*m*, *n*-*m*+1:*n*) contains the *m*-by-*m* upper triangular matrix *R*;
if $m \geq n$, the elements on and above the (*m*-*n*)th subdiagonal contain the *m*-by-*n* upper trapezoidal matrix *R*;
in both cases, the remaining elements, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of $\min(m,n)$ elementary reflectors.

<i>tau</i>	REAL for <i>sgerqf</i> DOUBLE PRECISION for <i>dgerqf</i> COMPLEX for <i>cgerqf</i> DOUBLE COMPLEX for <i>zgerqf</i> . Array, DIMENSION at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors for the matrix Q .
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gerqf* interface are the following:

<i>a</i>	Holds the matrix A of size (m, n) .
<i>tau</i>	Holds the vector of length $\min(m, n)$.

Application Notes

For better performance, try using $lwork = m * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Related routines include:

?orgrq	to generate matrix Q (for real matrices);
?ungrq	to generate matrix Q (for complex matrices);
?ormrq	to apply matrix Q (for real matrices);
?unmrq	to apply matrix Q (for complex matrices).

?orgrq

Generates the real matrix Q of the RQ factorization formed by ?gerqf.

Syntax

FORTRAN 77:

```
call sorgrq(m, n, k, a, lda, tau, work, lwork, info)
call dorgrq(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgrq(a, tau [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine generates an m -by- n real matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors $H(i)$ of order n : $Q = H(1) * H(2) * \dots * H(k)$ as returned by the routines [sgerqf/dgerqf](#). Use this routine after a call to [sgerqf/dgerqf](#).

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix Q ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix Q ($n \geq m$).

<i>k</i>	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
<i>a</i> , <i>tau</i> , <i>work</i>	REAL for <code>sorghr</code> DOUBLE PRECISION for <code>dorghr</code> Arrays: $a(lda,*)$, $tau(*)$. On entry, the $(m - k + i)$ -th row of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <code>sgerqf/dgerqf</code> in the last k rows of its array argument a ; $tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by <code>sgerqf/dgerqf</code> ; The second dimension of a must be at least $\max(1, n)$. The dimension of tau must be at least $\max(1, k)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of a ; at least $\max(1, m)$.
<i>lwork</i>	INTEGER. The size of the $work$ array; at least $\max(1, m)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of $lwork$.

Output Parameters

<i>a</i>	Overwritten by the m -by- n matrix Q .
$work(1)$	If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orghr` interface are the following:

a Holds the matrix *A* of size (m, n) .
tau Holds the vector of length (k) .

Application Notes

For better performance, try using $lwork = m * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value ($work(1)$) for subsequent runs.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?ungrq](#).

?ungrq

Generates the complex matrix Q of the RQ factorization formed by ?gerqf.

Syntax

FORTRAN 77:

```
call cungrq(m, n, k, a, lda, tau, work, lwork, info)
call zungrq(m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call ungrq(a, tau [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine generates an m -by- n complex matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors $H(i)$ of order n : $Q = H(1)H^*H(2)H^* \dots H(k)H^*$ as returned by the routines `sgerqf/dgerqf`. Use this routine after a call to `sgerqf/dgerqf`.

Input Parameters

m	INTEGER. The number of rows of the matrix Q ($m \geq 0$).
n	INTEGER. The number of columns of the matrix Q ($n \geq m$).
k	INTEGER. The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
$a, \tau, work$	REAL for <code>cungrq</code> DOUBLE PRECISION for <code>zungrq</code> Arrays: $a(lda,*)$, $\tau(*)$, $work(lwork)$. On entry, the $(m - k + i)$ th row of a must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by <code>sgerqf/dgerqf</code> in the last k rows of its array argument a ; $\tau(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by <code>sgerqf/dgerqf</code> ; The second dimension of a must be at least $\max(1, n)$. The dimension of τ must be at least $\max(1, k)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
$lwork$	INTEGER. The size of the $work$ array; at least $\max(1, m)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of $lwork$.

Output Parameters

<i>a</i>	Overwritten by the <i>m</i> -by- <i>n</i> matrix <i>Q</i> .
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ungrq` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>n</i>).

The real counterpart of this routine is [?orgrq](#).

?ormrq

Multiplies a real matrix by the orthogonal matrix Q of the RQ factorization formed by ?gerqf.

Syntax

FORTRAN 77:

```
call sormrq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call dormrq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormqr(a, tau, c [,side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the real orthogonal matrix defined as a product of k elementary reflectors H_i : $Q = H_1 H_2 \dots H_k$ as returned by the RQ factorization routine `sgerqf/dgerqf`.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products $Q^T C$, $Q^T C$, $C Q$, or $C Q^T$ (overwriting the result over C).

Input Parameters

<code>side</code>	CHARACTER*1. Must be either 'L' or 'R'. If <code>side</code> = 'L', Q or Q^T is applied to C from the left. If <code>side</code> = 'R', Q or Q^T is applied to C from the right.
<code>trans</code>	CHARACTER*1. Must be either 'N' or 'T'. If <code>trans</code> = 'N', the routine multiplies C by Q . If <code>trans</code> = 'T', the routine multiplies C by Q^T .
<code>m</code>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<code>n</code>	INTEGER. The number of columns in C ($n \geq 0$).
<code>k</code>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints:

$0 \leq k \leq m$, if *side* = 'L';
 $0 \leq k \leq n$, if *side* = 'R'.

a, *tau*, *c*, *work*

REAL for *sormrq*
 DOUBLE PRECISION for *dormrq*.
 Arrays: *a(lda,*)*, *tau(*)*, *c ldc,*)*.
 On entry, the *i*th row of *a* must contain the vector which defines the elementary reflector H_i , for $i = 1, 2, \dots, k$, as returned by *sgerqf/dgerqf* in the last *k* rows of its array argument *a*.
 The second dimension of *a* must be at least $\max(1, m)$ if *side* = 'L', and at least $\max(1, n)$ if *side* = 'R'.
tau(i) must contain the scalar factor of the elementary reflector H_i , as returned by *sgerqf/dgerqf*.
 The dimension of *tau* must be at least $\max(1, k)$.
c(ldc,)* contains the *m*-by-*n* matrix *C*.
 The second dimension of *c* must be at least $\max(1, n)$
work is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The first dimension of *a*; $lda \geq \max(1, k)$.

ldc

INTEGER. The first dimension of *c*; $ldc \geq \max(1, m)$.

lwork

INTEGER. The size of the *work* array. Constraints:
 $lwork \geq \max(1, n)$ if *side* = 'L';
 $lwork \geq \max(1, m)$ if *side* = 'R'.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

Output Parameters

c

Overwritten by the product $Q^T C$, $Q^T * C$, $C * Q$, or $C * Q^T$ (as specified by *side* and *trans*).

work(1)

If *info* = 0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormrq` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>k</i> , <i>m</i>).
<i>tau</i>	Holds the vector of length (<i>k</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n*blocksize$ (if *side* = 'L') or $lwork = m*blocksize$ (if *side* = 'R') where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?unmrq](#).

?unmrq

Multiplies a complex matrix by the unitary matrix Q of the RQ factorization formed by ?gerqf.

Syntax

FORTRAN 77:

```
call cunmrq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
call zunmrq(side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmrq(a, tau, c [,side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a complex m -by- n matrix C by Q or Q^H , where Q is the complex unitary matrix defined as a product of k elementary reflectors $H(i)$ of order n : $Q = H(1)H^*H(2)H^* \dots H(k)H^*$. Q has been returned by the RQ factorization routine `cgerqf/zgerqf`.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (overwriting the result over C).

Input Parameters

<code>side</code>	CHARACTER*1. Must be either 'L' or 'R'. If <code>side</code> = 'L', Q or Q^H is applied to C from the left. If <code>side</code> = 'R', Q or Q^H is applied to C from the right.
<code>trans</code>	CHARACTER*1. Must be either 'N' or 'C'. If <code>trans</code> = 'N', the routine multiplies C by Q . If <code>trans</code> = 'C', the routine multiplies C by Q^H .
<code>m</code>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<code>n</code>	INTEGER. The number of columns in C ($n \geq 0$).
<code>k</code>	INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints:

$0 \leq k \leq m$, if *side* = 'L';
 $0 \leq k \leq n$, if *side* = 'R'.

a, *tau*, *c*, *work*
 COMPLEX for *cunmrq*
 DOUBLE COMPLEX for *zunmrq*.
 Arrays: *a(lda,*)*, *tau(*)*, *c(ldc,*)*, *work(lwork)*.
 On entry, the *i*th row of *a* must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by *cgerqf/zgerqf* in the last *k* rows of its array argument *a*.
 The second dimension of *a* must be at least $\max(1, m)$ if *side* = 'L', and at least $\max(1, n)$ if *side* = 'R'.
tau(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by *cgerqf/zgerqf*.
 The dimension of *tau* must be at least $\max(1, k)$.
c(ldc,)* contains the *m*-by-*n* matrix *C*.
 The second dimension of *c* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda
 INTEGER. The first dimension of *a*; $lda \geq \max(1, k)$.

ldc
 INTEGER. The first dimension of *c*; $ldc \geq \max(1, m)$.

lwork
 INTEGER. The size of the *work* array. Constraints:
 $lwork \geq \max(1, n)$ if *side* = 'L';
 $lwork \geq \max(1, m)$ if *side* = 'R'.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.
 See *Application Notes* for the suggested value of *lwork*.

Output Parameters

c
 Overwritten by the product Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (as specified by *side* and *trans*).

work(1)
 If *info* = 0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmrq` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>k</i> , <i>m</i>).
<i>tau</i>	Holds the vector of length (<i>k</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, try using `lwork = n*blocksize` (if `side = 'L'`) or `lwork = m*blocksize` (if `side = 'R'`) where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is `?ormrq`.

?tzzrf

Reduces the upper trapezoidal matrix A to upper triangular form.

Syntax

FORTRAN 77:

```
call stzzrf(m, n, a, lda, tau, work, lwork, info)
call dtzzrf(m, n, a, lda, tau, work, lwork, info)
call ctzzrf(m, n, a, lda, tau, work, lwork, info)
call ztzzrf(m, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call tzzrf(a [, tau] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix A to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an n -by- n orthogonal/unitary matrix and R is an m -by- m upper triangular matrix.

See [?larz](#) that applies an elementary reflector returned by [?tzzrf](#) to a general matrix.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq m$).
$a, work$	REAL for <code>stzzrf</code> DOUBLE PRECISION for <code>dtzzrf</code> COMPLEX for <code>ctzzrf</code> DOUBLE COMPLEX for <code>ztzzrf</code> .

Arrays: $a(lda,*)$, $work(lwork)$. The leading m -by- n upper trapezoidal part of the array a contains the matrix A to be factorized.

The second dimension of a must be at least $\max(1, n)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The first dimension of a ; at least $\max(1, m)$.

lwork

INTEGER. The size of the $work$ array;

$lwork \geq \max(1, m)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a

Overwritten on exit by the factorization data as follows: the leading m -by- m upper triangular part of a contains the upper triangular matrix R , and elements $m + 1$ to n of the first m rows of a , with the array tau , represent the orthogonal matrix Z as a product of m elementary reflectors.

tau

REAL for `stzrzf`
 DOUBLE PRECISION for `dtzrzf`
 COMPLEX for `ctzrzf`
 DOUBLE COMPLEX for `ztzrzf`.

Array, DIMENSION at least $\max(1, m)$. Contains scalar factors of the elementary reflectors for the matrix Z .

work(1)

If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tzzrf` interface are the following:

`a` Holds the matrix A of size (m, n) .
`tau` Holds the vector of length (m) .

Application Notes

For better performance, try using `lwork = m*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Related routines include:

`?ormrz` to apply matrix Q (for real matrices)
`?unmrz` to apply matrix Q (for complex matrices).

?ormrz

Multiplies a real matrix by the orthogonal matrix defined from the factorization formed by ?tzrzf.

Syntax

FORTRAN 77:

```
call sormrz(side, trans, m, n, k, l, a, lda, tau, c, ldc, work, lwork, info)
call dormrz(side, trans, m, n, k, l, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormrz(a, tau, c, l [, side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a real m -by- n matrix C by Q or Q^T , where Q is the real orthogonal matrix defined as a product of k elementary reflectors $H(i)$ of order n : $Q = H(1) * H(2) * \dots * H(k)$ as returned by the factorization routine `stzrzf/dtzrzf`.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products $Q * C$, $Q^T * C$, $C * Q$, or $C * Q^T$ (overwriting the result over C).

The matrix Q is of order m if `side = 'L'` and of order n if `side = 'R'`.

Input Parameters

<code>side</code>	CHARACTER*1. Must be either 'L' or 'R'. If <code>side = 'L'</code> , Q or Q^T is applied to C from the left. If <code>side = 'R'</code> , Q or Q^T is applied to C from the right.
<code>trans</code>	CHARACTER*1. Must be either 'N' or 'T'. If <code>trans = 'N'</code> , the routine multiplies C by Q . If <code>trans = 'T'</code> , the routine multiplies C by Q^T .
<code>m</code>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<code>n</code>	INTEGER. The number of columns in C ($n \geq 0$).

k INTEGER. The number of elementary reflectors whose product defines the matrix Q . Constraints:
 $0 \leq k \leq m$, if *side* = 'L';
 $0 \leq k \leq n$, if *side* = 'R'.

l INTEGER.
The number of columns of the matrix A containing the meaningful part of the Householder reflectors. Constraints:
 $0 \leq l \leq m$, if *side* = 'L';
 $0 \leq l \leq n$, if *side* = 'R'.

a, *tau*, *c*, *work* REAL for *sormrz*
DOUBLE PRECISION for *dormrz*.
Arrays: *a*(*lda*,*), *tau*(*), *c*(*ldc*,*).
On entry, the *i*th row of *a* must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by *stzrzf/dtzrzf* in the last k rows of its array argument *a*.
The second dimension of *a* must be at least $\max(1, m)$ if *side* = 'L', and at least $\max(1, n)$ if *side* = 'R'.
tau(*i*) must contain the scalar factor of the elementary reflector $H(i)$, as returned by *stzrzf/dtzrzf*.
The dimension of *tau* must be at least $\max(1, k)$.
c(*ldc*,*) contains the m -by- n matrix C .
The second dimension of *c* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, k)$.

ldc INTEGER. The first dimension of *c*; $ldc \geq \max(1, m)$.

lwork INTEGER. The size of the *work* array. Constraints:
 $lwork \geq \max(1, n)$ if *side* = 'L';
 $lwork \geq \max(1, m)$ if *side* = 'R'.
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.
See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , Q^T*C , $C*Q$, or $C*Q^T$ (as specified by <i>side</i> and <i>trans</i>).
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormrz` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>k</i> , <i>m</i>).
<i>tau</i>	Holds the vector of length (<i>k</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n*blocksize$ (if *side* = 'L') or $lwork = m*blocksize$ (if *side* = 'R') where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex counterpart of this routine is [?unmrz](#).

?unmrz

Multiplies a complex matrix by the unitary matrix defined from the factorization formed by ?tzrzf.

Syntax

FORTRAN 77:

```
call cunmrz(side, trans, m, n, k, l, a, lda, tau, c, ldc, work, lwork, info)
call zunmrz(side, trans, m, n, k, l, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmrz(a, tau, c, l [,side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a complex m -by- n matrix C by Q or Q^H , where Q is the unitary matrix defined as a product of k elementary reflectors $H(i)$:

$$Q = H(1)H^* H(2)H^* \dots H(k)H$$

as returned by the factorization routine [ctzrzf/ztzrzf](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , $Q^H C$, C^*Q , or C^*Q^H (overwriting the result over C).

The matrix Q is of order m if *side* = 'L' and of order n if *side* = 'R'.

Input Parameters

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', Q or Q^H is applied to C from the left. If <i>side</i> = 'R', Q or Q^H is applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'C'. If <i>trans</i> = 'N', the routine multiplies C by Q .

If *trans* = 'C', the routine multiplies *c* by Q^H .

m INTEGER. The number of rows in the matrix *c* ($m \geq 0$).

n INTEGER. The number of columns in *c* ($n \geq 0$).

k INTEGER. The number of elementary reflectors whose product defines the matrix *Q*. Constraints:
 $0 \leq k \leq m$, if *side* = 'L';
 $0 \leq k \leq n$, if *side* = 'R'.

l INTEGER.
The number of columns of the matrix *A* containing the meaningful part of the Householder reflectors. Constraints:
 $0 \leq l \leq m$, if *side* = 'L';
 $0 \leq l \leq n$, if *side* = 'R'.

a, tau, c, work COMPLEX for *cunmrz*
DOUBLE COMPLEX for *zunmrz*.
Arrays: *a(lda,*)*, *tau(*)*, *c(ldc,*)*, *work(lwork)*.
On entry, the *i*th row of *a* must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by *ctzrzf/ztzrzf* in the last *k* rows of its array argument *a*.
The second dimension of *a* must be at least $\max(1, m)$ if *side* = 'L', and at least $\max(1, n)$ if *side* = 'R'.
tau(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by *ctzrzf/ztzrzf*.
The dimension of *tau* must be at least $\max(1, k)$.
c(ldc,)* contains the *m*-by-*n* matrix *C*.
The second dimension of *c* must be at least $\max(1, n)$
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; $lda \geq \max(1, k)$.

ldc INTEGER. The first dimension of *c*; $ldc \geq \max(1, m)$.

lwork INTEGER. The size of the *work* array. Constraints:
 $lwork \geq \max(1, n)$ if *side* = 'L';
 $lwork \geq \max(1, m)$ if *side* = 'R'.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`. See *Application Notes* for the suggested value of $lwork$.

Output Parameters

c	Overwritten by the product Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (as specified by $side$ and $trans$).
$work(1)$	If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmrz` interface are the following:

a	Holds the matrix A of size (k, m) .
tau	Holds the vector of length (k) .
c	Holds the matrix C of size (m, n) .
$side$	Must be 'L' or 'R'. The default value is 'L'.
$trans$	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n*blocksize$ (if $side = 'L'$) or $lwork = m*blocksize$ (if $side = 'R'$) where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real counterpart of this routine is [?ormrz](#).

?ggqrf

Computes the generalized QR factorization of two matrices.

Syntax

FORTRAN 77:

```
call sggqrf(n, m, p, a, lda, taua, b, ldb, taub, work, lwork, info)
call dggqrf(n, m, p, a, lda, taua, b, ldb, taub, work, lwork, info)
call cggqrf(n, m, p, a, lda, taua, b, ldb, taub, work, lwork, info)
call zggqrf(n, m, p, a, lda, taua, b, ldb, taub, work, lwork, info)
```

Fortran 95:

```
call ggqrf(a, b [,taua] [,taub] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine forms the generalized *QR* factorization of an *n*-by-*m* matrix *A* and an *n*-by-*p* matrix *B* as $A = Q^*R$, $B = Q^*T^*Z$, where *Q* is an *n*-by-*n* orthogonal/unitary matrix, *Z* is a *p*-by-*p* orthogonal/unitary matrix, and *R* and *T* assume one of the forms:

$$R = \begin{matrix} & & m \\ & m & \begin{pmatrix} R_{11} \\ 0 \end{pmatrix} \\ n - m & & \end{matrix}, \quad \text{if } n \geq m$$

or

$$R = \begin{matrix} & n & m - n \\ n & \begin{pmatrix} R_{11} & R_{12} \end{pmatrix} \\ & & \end{matrix}, \quad \text{if } n < m$$

where R_{11} is upper triangular, and

$$T = \begin{matrix} & p - n & n \\ n & \begin{pmatrix} 0 & T_{12} \end{pmatrix} \\ & & \end{matrix}, \quad \text{if } n \leq p,$$

$$T = \begin{matrix} & & p \\ n - p & \begin{pmatrix} T_{11} \\ T_{21} \end{pmatrix} \\ p & & \end{matrix}, \quad \text{if } n > p,$$

where T_{12} or T_{21} is a p -by- p upper triangular matrix.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of $B^{-1}A$ as:

$$B^{-1}A = Z^H (T^{-1}R)$$

Input Parameters

n INTEGER. The number of rows of the matrices A and B ($n \geq 0$).

m INTEGER. The number of columns in A ($m \geq 0$).

p INTEGER. The number of columns in *B* ($p \geq 0$).

a, b, work REAL for sggqrf
 DOUBLE PRECISION for dggqrf
 COMPLEX for cggqrf
 DOUBLE COMPLEX for zggqrf.
 Arrays: *a(lda,*)* contains the matrix *A*.
 The second dimension of *a* must be at least $\max(1, m)$.
b(l db,)* contains the matrix *B*.
 The second dimension of *b* must be at least $\max(1, p)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

ldb INTEGER. The first dimension of *b*; at least $\max(1, n)$.

lwork INTEGER. The size of the *work* array; must be at least $\max(1, n, m, p)$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a, b Overwritten by the factorization data as follows:
 on exit, the elements on and above the diagonal of the array *a* contain the $\min(n,m)$ -by-*m* upper trapezoidal matrix *R* (*R* is upper triangular if $n \geq m$); the elements below the diagonal, with the array *taua*, represent the orthogonal/unitary matrix *Q* as a product of $\min(n,m)$ elementary reflectors ;
 if $n \leq p$, the upper triangle of the subarray *b*(1:*n*, *p*-*n*+1:*p*) contains the *n*-by-*n* upper triangular matrix *T*;
 if $n > p$, the elements on and above the (*n*-*p*)th subdiagonal contain the *n*-by-*p* upper trapezoidal matrix *T*; the remaining elements, with the array *taub*, represent the orthogonal/unitary matrix *Z* as a product of elementary reflectors.

taua, taub REAL for sggqrf

DOUBLE PRECISION for `dggqrf`
 COMPLEX for `cggqrf`
 DOUBLE COMPLEX for `zggqrf`.
 Arrays, DIMENSION at least $\max(1, \min(n, m))$ for *taua* and
 at least $\max(1, \min(n, p))$ for *taub*. The array *taua* contains
 the scalar factors of the elementary reflectors which
 represent the orthogonal/unitary matrix *Q*.
 The array *taub* contains the scalar factors of the elementary
 reflectors which represent the orthogonal/unitary matrix *Z*.
work(1) If *info* = 0, on exit *work*(1) contains the minimum value
 of *lwork* required for optimum performance. Use this *lwork*
 for subsequent runs.
info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggqrf` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, m) .
<i>b</i>	Holds the matrix <i>B</i> of size (n, p) .
<i>taua</i>	Holds the vector of length $\min(n, m)$.
<i>taub</i>	Holds the vector of length $\min(n, p)$.

Application Notes

For better performance, try using $lwork \geq \max(n, m, p) * \max(nb1, nb2, nb3)$, where *nb1* is the optimal blocksize for the *QR* factorization of an *n*-by-*m* matrix, *nb2* is the optimal blocksize for the *RQ* factorization of an *n*-by-*p* matrix, and *nb3* is the optimal blocksize for a call of `?or-mqr/?unmqr`.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?ggrqf

Computes the generalized RQ factorization of two matrices.

Syntax

FORTRAN 77:

```
call sggrqf (m, p, n, a, lda, taua, b, ldb, taub, work, lwork, info)
call dggrqf (m, p, n, a, lda, taua, b, ldb, taub, work, lwork, info)
call cggrqf (m, p, n, a, lda, taua, b, ldb, taub, work, lwork, info)
call zggrqf (m, p, n, a, lda, taua, b, ldb, taub, work, lwork, info)
```

Fortran 95:

```
call ggrqf(a, b [,taua] [,taub] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine forms the generalized *RQ* factorization of an *m*-by-*n* matrix *A* and an *p*-by-*n* matrix *B* as $A = R*Q$, $B = Z*T*Q$, where *Q* is an *n*-by-*n* orthogonal/unitary matrix, *Z* is a *p*-by-*p* orthogonal/unitary matrix, and *R* and *T* assume one of the forms:

$$R = \begin{matrix} n - m & m \\ m & \end{matrix} \begin{pmatrix} 0 & R_{12} \end{pmatrix}, \quad \text{if } m \leq n,$$

or

$$R = \begin{matrix} m - n & n \\ n & \end{matrix} \begin{pmatrix} R_{11} \\ R_{21} \end{pmatrix}, \quad \text{if } m > n,$$

where R_{11} or R_{21} is upper triangular, and

$$T = \begin{matrix} n \\ p - n & \end{matrix} \begin{pmatrix} T_{11} \\ 0 \end{pmatrix}, \quad \text{if } p \geq n,$$

or

$$T = \begin{matrix} p & n - p \\ p & \end{matrix} \begin{pmatrix} T_{11} & T_{12} \end{pmatrix}, \quad \text{if } p < n,$$

where T_{11} is upper triangular.

In particular, if B is square and nonsingular, the *GRQ* factorization of A and B implicitly gives the *RQ* factorization of A^*B^{-1} as:

$$A^*B^{-1} = (R^*T^{-1})^*Z^H$$

Input Parameters

m INTEGER. The number of rows of the matrix A ($m \geq 0$).

p	INTEGER. The number of rows in B ($p \geq 0$).
n	INTEGER. The number of columns of the matrices A and B ($n \geq 0$).
$a, b, work$	REAL for <code>sggrqf</code> DOUBLE PRECISION for <code>dggrqf</code> COMPLEX for <code>cggrqf</code> DOUBLE COMPLEX for <code>zggrqf</code> . Arrays: $a(lda,*)$ contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$. $b(l db,*)$ contains the p -by- n matrix B . The second dimension of b must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
ldb	INTEGER. The first dimension of b ; at least $\max(1, p)$.
$lwork$	INTEGER. The size of the $work$ array; must be at least $\max(1, n, m, p)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of $lwork$.

Output Parameters

a, b	Overwritten by the factorization data as follows: on exit, if $m \leq n$, the upper triangle of the subarray $a(1:m, n-m+1:n)$ contains the m -by- m upper triangular matrix R ; if $m > n$, the elements on and above the $(m-n)$ th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array $taua$, represent the orthogonal/unitary matrix Q as a product of elementary reflectors; the elements on and above the diagonal of the array b contain the $\min(p, n)$ -by- n upper trapezoidal matrix T (T is upper triangular if $p \geq n$); the elements below the
--------	--

diagonal, with the array *taub*, represent the orthogonal/unitary matrix *Z* as a product of elementary reflectors.

taua, taub REAL for *sggrqf*
 DOUBLE PRECISION for *dggrqf*
 COMPLEX for *cggrqf*
 DOUBLE COMPLEX for *zggrqf*.
 Arrays, DIMENSION at least $\max(1, \min(m, n))$ for *taua* and at least $\max(1, \min(p, n))$ for *taub*.
 The array *taua* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Q*.
 The array *taub* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Z*.

work(1) If *info* = 0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ggrqf* interface are the following:

a Holds the matrix *A* of size (m, n) .
b Holds the matrix *A* of size (p, n) .
taua Holds the vector of length $\min(m, n)$.
taub Holds the vector of length $\min(p, n)$.

Application Notes

For better performance, try using

$$lwork \geq \max(n, m, p) * \max(nb1, nb2, nb3),$$

where $nb1$ is the optimal blocksize for the RQ factorization of an m -by- n matrix, $nb2$ is the optimal blocksize for the QR factorization of an p -by- n matrix, and $nb3$ is the optimal blocksize for a call of `?ormrq/?unmrq`.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Singular Value Decomposition

This section describes LAPACK routines for computing the *singular value decomposition* (SVD) of a general m -by- n matrix A :

$$A = U\Sigma V^H.$$

In this decomposition, U and V are unitary (for complex A) or orthogonal (for real A); Σ is an m -by- n diagonal matrix with real diagonal elements σ_i :

$$\sigma_1 < \sigma_2 < \dots < \sigma_{\min(m, n)} < 0.$$

The diagonal elements σ_i are *singular values* of A . The first $\min(m, n)$ columns of the matrices U and V are, respectively, *left* and *right singular vectors* of A . The singular values and singular vectors satisfy

$$Av_i = \sigma_i u_i \text{ and } A^H u_i = \sigma_i v_i$$

where u_i and v_i are the i -th columns of U and V , respectively.

To find the SVD of a general matrix A , call the LAPACK routine `?gebrd` or `?gbbbrd` for reducing A to a bidiagonal matrix B by a unitary (orthogonal) transformation: $A = QBP^H$. Then call `?bdsqr`, which forms the SVD of a bidiagonal matrix: $B = U_1 \Sigma V_1^H$.

Thus, the sought-for SVD of A is given by $A = U\Sigma V^H = (QU_1)\Sigma(V_1^HP^H)$.

Table 4-2 lists LAPACK routines (FORTRAN 77 interface) that perform singular value decomposition of matrices. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-2 Computational Routines for Singular Value Decomposition (SVD)

Operation	Real matrices	Complex matrices
Reduce A to a bidiagonal matrix B : $A = QB P^H$ (full storage)	?gebrd	?gebrd
Reduce A to a bidiagonal matrix B : $A = QB P^H$ (band storage)	?gbbbrd	?gbbbrd
Generate the orthogonal (unitary) matrix Q or P	?orgbr	?ungbr
Apply the orthogonal (unitary) matrix Q or P	?ormbr	?unmbr
Form singular value decomposition of the bidiagonal matrix B : $B = U\Sigma V^H$?bdsqr ?bdsdc	?bdsqr

Figure 4-1 Decision Tree: Singular Value Decomposition

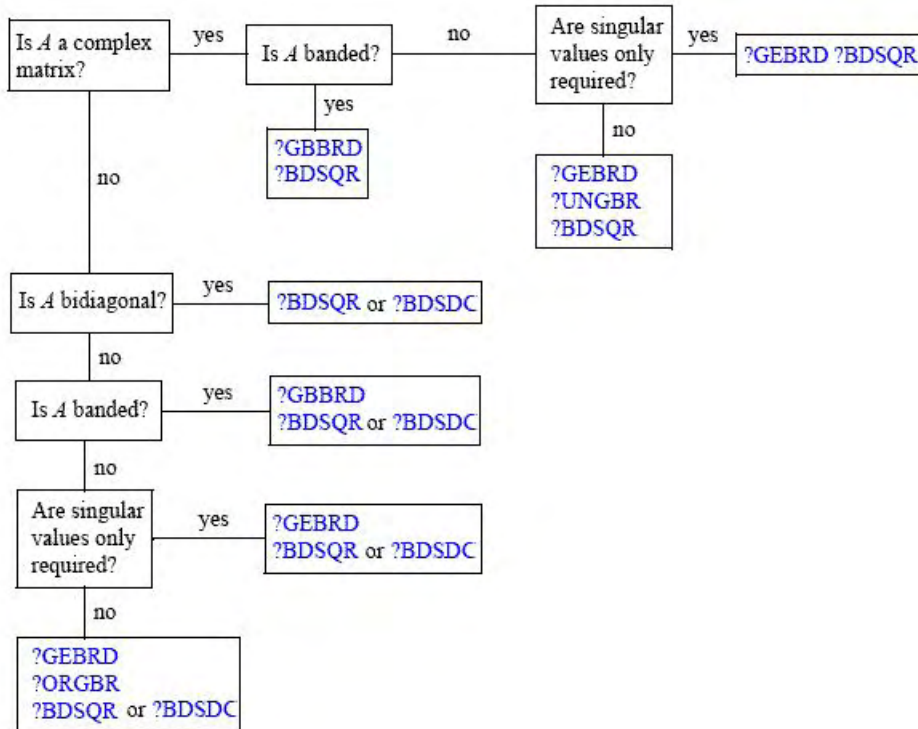

Figure 4-1 “Decision Tree: Singular Value Decomposition” presents a decision tree that helps you choose the right sequence of routines for SVD, depending on whether you need singular values only or singular vectors as well, whether A is real or complex, and so on.

You can use the SVD to find a minimum-norm solution to a (possibly) rank-deficient least squares problem of minimizing $\|Ax - b\|^2$. The effective rank k of the matrix A can be determined as the number of singular values which exceed a suitable threshold. The minimum-norm solution is

$$x = V_k(\Sigma_k)^{-1}c$$

where Σ_k is the leading k -by- k submatrix of Σ , the matrix V_k consists of the first k columns of $V = PV_1$, and the vector c consists of the first k elements of $U^H b = U_1^H Q^H b$.

?gebrd

Reduces a general matrix to bidiagonal form.

Syntax

FORTRAN 77:

```
call sgebrd(m, n, a, lda, d, e, tauq, taup, work, lwork, info)
call dgebrd(m, n, a, lda, d, e, tauq, taup, work, lwork, info)
call cgebrd(m, n, a, lda, d, e, tauq, taup, work, lwork, info)
call zgebrd(m, n, a, lda, d, e, tauq, taup, work, lwork, info)
```

Fortran 95:

```
call gebrd(a [, d] [,e] [,tauq] [,taup] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reduces a general m -by- n matrix A to a bidiagonal matrix B by an orthogonal (unitary) transformation.

$$A = QBP^H = Q \begin{pmatrix} B_1 \\ 0 \end{pmatrix} P^H = Q_1 B_1 P^H,$$

If $m \geq n$, the reduction is given by

where B_1 is an n -by- n upper diagonal matrix, Q and P are orthogonal or, for a complex A , unitary matrices; Q_1 consists of the first n columns of Q .

If $m < n$, the reduction is given by

$$A = Q^* B^* P^H = Q^* (B_1 0) P^H = Q_1^* B_1^* P_1^H,$$

where B_1 is an m -by- m lower diagonal matrix, Q and P are orthogonal or, for a complex A , unitary matrices; P_1 consists of the first m rows of P .

The routine does not form the matrices Q and P explicitly, but represents them as products of elementary reflectors. Routines are provided to work with the matrices Q and P in this representation:

If the matrix A is real,

- to compute Q and P explicitly, call `?orgbr`.
- to multiply a general matrix by Q or P , call `?ormbr`.

If the matrix A is complex,

- to compute Q and P explicitly, call `?ungbr`.
- to multiply a general matrix by Q or P , call `?unmbr`.

Input Parameters

m	INTEGER. The number of rows in the matrix A ($m \geq 0$).
n	INTEGER. The number of columns in A ($n \geq 0$).
$a, work$	REAL for <code>sgebrd</code> DOUBLE PRECISION for <code>dgebrd</code> COMPLEX for <code>cgebrd</code> DOUBLE COMPLEX for <code>zgebrd</code> . Arrays: $a(lda,*)$ contains the matrix A . The second dimension of a must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
$lwork$	INTEGER. The dimension of $work$; at least $\max(1, m, n)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of $lwork$.

Output Parameters

a	If $m \geq n$, the diagonal and first super-diagonal of a are overwritten by the upper bidiagonal matrix B . Elements below the diagonal are overwritten by details of Q , and the remaining elements are overwritten by details of P .
-----	--

If $m < n$, the diagonal and first sub-diagonal of a are overwritten by the lower bidiagonal matrix B . Elements above the diagonal are overwritten by details of P , and the remaining elements are overwritten by details of Q .

<i>d</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, DIMENSION at least $\max(1, \min(m, n))$. Contains the diagonal elements of B .
<i>e</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, DIMENSION at least $\max(1, \min(m, n) - 1)$. Contains the off-diagonal elements of B .
<i>tauq, tauq</i>	REAL for sgebrd DOUBLE PRECISION for dgebrd COMPLEX for cgebrd DOUBLE COMPLEX for zgebrd. Arrays, DIMENSION at least $\max(1, \min(m, n))$. Contain further details of the matrices Q and P .
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gebrd* interface are the following:

<i>a</i>	Holds the matrix A of size (m, n) .
<i>d</i>	Holds the vector of length $\min(m, n)$.
<i>e</i>	Holds the vector of length $\min(m, n) - 1$.
<i>tauq</i>	Holds the vector of length $\min(m, n)$.
<i>tauq</i>	Holds the vector of length $\min(m, n)$.

Application Notes

For better performance, try using $lwork = (m + n) * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrices Q , B , and P satisfy $QB P^H = A + E$, where $\|E\|_2 = c(n)\epsilon \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations for real flavors is

$$(4/3) * n^2 * (3 * m - n) \text{ for } m \geq n,$$

$$(4/3) * m^2 * (3 * n - m) \text{ for } m < n.$$

The number of operations for complex flavors is four times greater.

If n is much less than m , it can be more efficient to first form the QR factorization of A by calling [?geqrf](#) and then reduce the factor R to bidiagonal form. This requires approximately $2 * n^2 * (m + n)$ floating-point operations.

If m is much less than n , it can be more efficient to first form the LQ factorization of A by calling [?gelqf](#) and then reduce the factor L to bidiagonal form. This requires approximately $2 * m^2 * (m + n)$ floating-point operations.

?gbbbrd

Reduces a general band matrix to bidiagonal form.

Syntax

FORTRAN 77:

```
call sgbbrd(vect, m, n, ncc, kl, ku, ab, ldab, d, e, q, ldq, pt, ldpt, c, ldc,
work, info)
```

```
call dgbbrd(vect, m, n, ncc, kl, ku, ab, ldab, d, e, q, ldq, pt, ldpt, c, ldc,
work, info)
```

```
call cgbbrd(vect, m, n, ncc, kl, ku, ab, ldab, d, e, q, ldq, pt, ldpt, c, ldc,
work, rwork, info)
```

```
call zgbbrd(vect, m, n, ncc, kl, ku, ab, ldab, d, e, q, ldq, pt, ldpt, c, ldc,
work, rwork, info)
```

Fortran 95:

```
call gbbbrd(ab [, c] [,d] [,e] [,q] [,pt] [,kl] [,m] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine reduces an m -by- n band matrix A to upper bidiagonal matrix B : $A = Q * B * P^H$. Here the matrices Q and P are orthogonal (for real A) or unitary (for complex A). They are determined as products of Givens rotation matrices, and may be formed explicitly by the routine if required. The routine can also update a matrix C as follows: $C = Q^H * C$.

Input Parameters

<i>vect</i>	CHARACTER*1. Must be 'N' or 'Q' or 'P' or 'B'. If <i>vect</i> = 'N', neither Q nor P^H is generated. If <i>vect</i> = 'Q', the routine generates the matrix Q . If <i>vect</i> = 'P', the routine generates the matrix P^H . If <i>vect</i> = 'B', the routine generates both Q and P^H .
<i>m</i>	INTEGER. The number of rows in the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in A ($n \geq 0$).

<i>ncc</i>	INTEGER. The number of columns in <i>c</i> ($ncc \geq 0$).
<i>kl</i>	INTEGER. The number of sub-diagonals within the band of <i>A</i> ($kl \geq 0$).
<i>ku</i>	INTEGER. The number of super-diagonals within the band of <i>A</i> ($ku \geq 0$).
<i>ab, c, work</i>	<p>REAL for sgbbrd DOUBLE PRECISION for dgbbrd COMPLEX for cgbbrd DOUBLE COMPLEX for zgbbrd.</p> <p>Arrays: <i>ab(ldab,*)</i> contains the matrix <i>A</i> in band storage (see Matrix Storage Schemes). The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>c ldc,*)</i> contains an <i>m</i>-by-<i>ncc</i> matrix <i>C</i>. If $ncc = 0$, the array <i>c</i> is not referenced. The second dimension of <i>c</i> must be at least $\max(1, ncc)$. <i>work(*)</i> is a workspace array. The dimension of <i>work</i> must be at least $2 \cdot \max(m, n)$ for real flavors, or $\max(m, n)$ for complex flavors.</p>
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ($ldab \geq kl + ku + 1$).
<i>ldq</i>	<p>INTEGER. The first dimension of the output array <i>q</i>. $ldq \geq \max(1, m)$ if <i>vect</i> = 'Q' or 'B', $ldq \geq 1$ otherwise.</p>
<i>ldpt</i>	<p>INTEGER. The first dimension of the output array <i>pt</i>. $ldpt \geq \max(1, n)$ if <i>vect</i> = 'P' or 'B', $ldpt \geq 1$ otherwise.</p>
<i>ldc</i>	<p>INTEGER. The first dimension of the array <i>c</i>. $ldc \geq \max(1, m)$ if $ncc > 0$; $ldc \geq 1$ if $ncc = 0$.</p>
<i>rwork</i>	<p>REAL for cgbbrd DOUBLE PRECISION for zgbbrd. A workspace array, DIMENSION at least $\max(m, n)$.</p>

Output Parameters

<i>ab</i>	Overwritten by values generated during the reduction.
-----------	---

<i>d</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, DIMENSION at least $\max(1, \min(m, n))$. Contains the diagonal elements of the matrix <i>B</i> .
<i>e</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, DIMENSION at least $\max(1, \min(m, n) - 1)$. Contains the off-diagonal elements of <i>B</i> .
<i>q, pt</i>	REAL for sgebrd DOUBLE PRECISION for dgebrd COMPLEX for cgebrd DOUBLE COMPLEX for zgebrd. Arrays: <i>q</i> (<i>ldq</i> , *) contains the output <i>m</i> -by- <i>m</i> matrix <i>Q</i> . The second dimension of <i>q</i> must be at least $\max(1, m)$. <i>p</i> (<i>ldpt</i> , *) contains the output <i>n</i> -by- <i>n</i> matrix <i>P</i> ^T . The second dimension of <i>pt</i> must be at least $\max(1, n)$.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gbbbrd* interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size $(kl+ku+1, n)$.
<i>c</i>	Holds the matrix <i>C</i> of size (m, ncc) .
<i>d</i>	Holds the vector with the number of elements $\min(m, n)$.
<i>e</i>	Holds the vector with the number fo elements $\min(m, n)-1$.
<i>q</i>	Holds the matrix <i>Q</i> of size (m, m) .
<i>pt</i>	Holds the matrix <i>PT</i> of size (n, n) .
<i>m</i>	If omitted, assumed $m = n$.
<i>kl</i>	If omitted, assumed $kl = ku$.
<i>ku</i>	Restored as $ku = lda-kl-1$.

vect Restored based on the presence of arguments *q* and *pt* as follows:
vect = 'B', if both *q* and *pt* are present,
vect = 'Q', if *q* is present and *pt* omitted, *vect* = 'P',
if *q* is omitted and *pt* present, *vect* = 'N', if both *q* and *pt* are omitted.

Application Notes

The computed matrices *Q*, *B*, and *P* satisfy $Q^*B^*P^H = A + E$, where $\|E\|_2 = c(n)\epsilon \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

If $m = n$, the total number of floating-point operations for real flavors is approximately the sum of:

- $6*n^2*(kl + ku)$ if *vect* = 'N' and *ncc* = 0,
- $3*n^2*ncc*(kl + ku - 1)/(kl + ku)$ if *C* is updated, and
- $3*n^3*(kl + ku - 1)/(kl + ku)$ if either *Q* or *P^H* is generated (double this if both).

To estimate the number of operations for complex flavors, use the same formulas with the coefficients 20 and 10 (instead of 6 and 3).

?orgbr

Generates the real orthogonal matrix Q or P^T determined by ?gebrd.

Syntax

FORTRAN 77:

```
call sorgbr(vect, m, n, k, a, lda, tau, work, lwork, info)
call dorgbr(vect, m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgbr(a, tau [,vect] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine generates the whole or part of the orthogonal matrices Q and P_T formed by the routines `sgebrd/dgebrd`. Use this routine after a call to `sgebrd/dgebrd`. All valid combinations of arguments are described in *Input parameters*. In most cases you need the following:

To compute the whole m -by- m matrix Q :

```
call ?orgbr('Q', m, m, n, a ... )
```

(note that the array a must have at least m columns).

To form the n leading columns of Q if $m > n$:

```
call ?orgbr('Q', m, n, n, a ... )
```

To compute the whole n -by- n matrix P^T :

```
call ?orgbr('P', n, n, m, a ... )
```

(note that the array a must have at least n rows).

To form the m leading rows of P_T if $m < n$:

```
call ?orgbr('P', m, n, m, a ... )
```

Input Parameters

$vect$	CHARACTER*1. Must be 'Q' or 'P'. If $vect = 'Q'$, the routine generates the matrix Q . If $vect = 'P'$, the routine generates the matrix P^T .
m	INTEGER. The number of required rows of Q or P^T .
n	INTEGER. The number of required columns of Q or P^T .
k	INTEGER. One of the dimensions of A in <code>?gebrd</code> : If $vect = 'Q'$, the number of columns in A ; If $vect = 'P'$, the number of rows in A . Constraints: $m \geq 0, n \geq 0, k \geq 0$. For $vect = 'Q'$: $k \leq n \leq m$ if $m > k$, or $m = n$ if $m \leq k$. For $vect = 'P'$: $k \leq m \leq n$ if $n > k$, or $m = n$ if $n \leq k$.
$a, work$	REAL for <code>sorgbr</code> DOUBLE PRECISION for <code>dorgbr</code> . Arrays: $a(lda,*)$ is the array a as returned by <code>?gebrd</code> . The second dimension of a must be at least $\max(1, n)$. $work$ is a workspace array, its dimension $\max(1, lwork)$.

<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>tau</i>	REAL for <i>sorgbr</i> DOUBLE PRECISION for <i>dorgbr</i> . For <i>vect</i> = 'Q', the array <i>tauq</i> as returned by <i>?gebrd</i> . For <i>vect</i> = 'P', the array <i>taup</i> as returned by <i>?gebrd</i> . The dimension of <i>tau</i> must be at least $\max(1, \min(m, k))$ for <i>vect</i> = 'Q', or $\max(1, \min(m, k))$ for <i>vect</i> = 'P'.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by the orthogonal matrix <i>Q</i> or P^T (or the leading rows or columns thereof) as specified by <i>vect</i> , <i>m</i> , and <i>n</i> .
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *orgbr* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m, n) .
<i>tau</i>	Holds the vector of length $\min(m, k)$ where $k = m$, if <i>vect</i> = 'P', $k = n$, if <i>vect</i> = 'Q'.
<i>vect</i>	Must be 'Q' or 'P'. The default value is 'Q'.

Application Notes

For better performance, try using $lwork = \min(m, n) * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\epsilon)$.

The approximate numbers of floating-point operations for the cases listed in *Description* are as follows:

To form the whole of Q :

$$(4/3) * n * (3m^2 - 3m * n + n^2) \text{ if } m > n;$$

$$(4/3) * m^3 \text{ if } m \leq n.$$

To form the n leading columns of Q when $m > n$:

$$(2/3) * n^2 * (3m - n^2) \text{ if } m > n.$$

To form the whole of P^T :

$$(4/3) * n^3 \text{ if } m \geq n;$$

$$(4/3) * m * (3n^2 - 3m * n + m^2) \text{ if } m < n.$$

To form the m leading columns of P^T when $m < n$:

$$(2/3) * n^2 * (3m - n^2) \text{ if } m > n.$$

The complex counterpart of this routine is [?ungbr](#).

?ormbr

Multiplies an arbitrary real matrix by the real orthogonal matrix Q or P^T determined by ?gebrd.

Syntax

FORTRAN 77:

```
call sormbr(vect, side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

```
call dormbr(vect, side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormbr(a, tau, c [,vect] [,side] [,trans] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

Given an arbitrary real matrix C , this routine forms one of the matrix products $Q^T * C$, $Q * C$, $C * Q$, $C * Q^T$, $P * C$, $P^T * C$, $C * P$, $C * P^T$, where Q and P are orthogonal matrices computed by a call to [sgebrd/dgebrd](#). The routine overwrites the product on C .

Input Parameters

In the descriptions below, r denotes the order of Q or P^T :

If $side = 'L'$, $r = m$; if $side = 'R'$, $r = n$.

<i>vect</i>	CHARACTER*1. Must be 'Q' or 'P'. If <i>vect</i> = 'Q', then Q or Q^T is applied to C . If <i>vect</i> = 'P', then P or P^T is applied to C .
<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', multipliers are applied to C from the left. If <i>side</i> = 'R', they are applied to C from the right.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T'. If <i>trans</i> = 'N', then Q or P is applied to C .

If $trans = 'T'$, then Q^T or P^T is applied to C .

m INTEGER. The number of rows in C .

n INTEGER. The number of columns in C .

k INTEGER. One of the dimensions of A in `?gebrd`:
 If $vect = 'Q'$, the number of columns in A ;
 If $vect = 'P'$, the number of rows in A .
 Constraints: $m \geq 0$, $n \geq 0$, $k \geq 0$.

$a, c, work$ REAL for `sormbr`
 DOUBLE PRECISION for `dormbr`.
 Arrays:
 $a(lda,*)$ is the array a as returned by `?gebrd`.
 Its second dimension must be at least $\max(1, \min(r, k))$ for
 $vect = 'Q'$, or $\max(1, r)$ for $vect = 'P'$.
 $c(ldc,*)$ holds the matrix C .
 Its second dimension must be at least $\max(1, n)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of a . Constraints:
 $lda \geq \max(1, r)$ if $vect = 'Q'$;
 $lda \geq \max(1, \min(r, k))$ if $vect = 'P'$.

ldc INTEGER. The first dimension of c ; $ldc \geq \max(1, m)$.

tau REAL for `sormbr`
 DOUBLE PRECISION for `dormbr`.
 Array, DIMENSION at least $\max(1, \min(r, k))$.
 For $vect = 'Q'$, the array $tauq$ as returned by `?gebrd`.
 For $vect = 'P'$, the array $taup$ as returned by `?gebrd`.

$lwork$ INTEGER. The size of the $work$ array. Constraints:
 $lwork \geq \max(1, n)$ if $side = 'L'$;
 $lwork \geq \max(1, m)$ if $side = 'R'$.
 If $lwork = -1$, then a workspace query is assumed; the
 routine only calculates the optimal size of the $work$ array,
 returns this value as the first entry of the $work$ array, and
 no error message related to $lwork$ is issued by `xerbla`.
 See *Application Notes* for the suggested value of $lwork$.

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , Q^T*C , $C*Q$, $C*Q^T$, P^*C , P^T*C , C^*P , or C^*P^T , as specified by <i>vect</i> , <i>side</i> , and <i>trans</i> .
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormbr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size $(r, \min(nq, k))$ where $r = nq$, if <i>vect</i> = 'Q', $r = \min(nq, k)$, if <i>vect</i> = 'P', $nq = m$, if <i>side</i> = 'L', $nq = n$, if <i>side</i> = 'R', $k = m$, if <i>vect</i> = 'P', $k = n$, if <i>vect</i> = 'Q'.
<i>tau</i>	Holds the vector of length $\min(nq, k)$.
<i>c</i>	Holds the matrix <i>C</i> of size (m, n) .
<i>vect</i>	Must be 'Q' or 'P'. The default value is 'Q'.
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using

lwork = *n***blocksize* for *side* = 'L', or

lwork = *m***blocksize* for *side* = 'R',

where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed product differs from the exact product by a matrix *E* such that $\|E\|_2 = O(\varepsilon) * \|C\|_2$.

The total number of floating-point operations is approximately

$2*n*k(2*m - k)$ if *side* = 'L' and $m \geq k$;

$2*m*k(2*n - k)$ if *side* = 'R' and $n \geq k$;

$2*m^2*n$ if *side* = 'L' and $m < k$;

$2*n^2*m$ if *side* = 'R' and $n < k$.

The complex counterpart of this routine is [?unmbr](#).

?ungbr

Generates the complex unitary matrix *Q* or *P^H* determined by [?gebrd](#).

Syntax

FORTRAN 77:

```
call cungbr(vect, m, n, k, a, lda, tau, work, lwork, info)
call zungbr(vect, m, n, k, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call ungbr(a, tau [,vect] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine generates the whole or part of the unitary matrices Q and P_H formed by the routines [cgebrd/zgebrd](#). Use this routine after a call to [cgebrd/zgebrd](#). All valid combinations of arguments are described in *Input Parameters*; in most cases you need the following:

To compute the whole m -by- m matrix Q , use:

```
call ?ungbr('Q', m, m, n, a ... )
```

(note that the array a must have at least m columns).

To form the n leading columns of Q if $m > n$, use:

```
call ?ungbr('Q', m, n, n, a ... )
```

To compute the whole n -by- n matrix P^H , use:

```
call ?ungbr('P', n, n, m, a ... )
```

(note that the array a must have at least n rows).

To form the m leading rows of P_H if $m < n$, use:

```
call ?ungbr('P', m, n, m, a ... )
```

Input Parameters

<i>vect</i>	CHARACTER*1. Must be 'Q' or 'P'. If <i>vect</i> = 'Q', the routine generates the matrix Q . If <i>vect</i> = 'P', the routine generates the matrix P^H .
<i>m</i>	INTEGER. The number of required rows of Q or P^H .
<i>n</i>	INTEGER. The number of required columns of Q or P^H .
<i>k</i>	INTEGER. One of the dimensions of A in ?gebrd : If <i>vect</i> = 'Q', the number of columns in A ; If <i>vect</i> = 'P', the number of rows in A .
	Constraints: $m \geq 0$, $n \geq 0$, $k \geq 0$. For <i>vect</i> = 'Q': $k \leq n \leq m$ if $m > k$, or $m = n$ if $m \leq k$.

For $vect = 'P'$: $k \leq m \leq n$ if $n > k$, or $m = n$ if $n \leq k$.

$a, work$ COMPLEX for `cungbr`
DOUBLE COMPLEX for `zungbr`.

Arrays:
 $a(lda,*)$ is the array a as returned by `?gebrd`.
The second dimension of a must be at least $\max(1, n)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of a ; at least $\max(1, m)$.

tau COMPLEX for `cungbr`
DOUBLE COMPLEX for `zungbr`.
For $vect = 'Q'$, the array $tauq$ as returned by `?gebrd`.
For $vect = 'P'$, the array $taup$ as returned by `?gebrd`.
The dimension of tau must be at least $\max(1, \min(m, k))$ for $vect = 'Q'$, or $\max(1, \min(m, k))$ for $vect = 'P'$.

$lwork$ INTEGER. The size of the $work$ array.
Constraint: $lwork < \max(1, \min(m, n))$.
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.
See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a Overwritten by the orthogonal matrix Q or P^T (or the leading rows or columns thereof) as specified by $vect$, m , and n .

$work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$ INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ungbr` interface are the following:

<code>a</code>	Holds the matrix A of size (m, n) .
<code>tau</code>	Holds the vector of length $\min(m, k)$ where $k = m$, if <code>vect</code> = 'P', $k = n$, if <code>vect</code> = 'Q'.
<code>vect</code>	Must be 'Q' or 'P'. The default value is 'Q'.

Application Notes

For better performance, try using `lwork = min(m, n)*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork = -1`.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork = -1`, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\epsilon)$.

The approximate numbers of possible floating-point operations are listed below:

To compute the whole matrix Q :

$(16/3)n(3m^2 - 3m*n + n^2)$ if $m > n$;

$(16/3)m^3$ if $m \leq n$.

To form the n leading columns of Q when $m > n$:

$$(8/3)n^2(3m - n^2).$$

To compute the whole matrix P^H :

$$(16/3)n^3 \text{ if } m \geq n;$$

$$(16/3)m(3n^2 - 3m*n + m^2) \text{ if } m < n.$$

To form the m leading columns of P^H when $m < n$:

$$(8/3)n^2(3m - n^2) \text{ if } m > n.$$

The real counterpart of this routine is [?orgbr](#).

?unmbr

Multiplies an arbitrary complex matrix by the unitary matrix Q or P determined by ?gebrd.

Syntax

FORTRAN 77:

```
call cunmbr(vect, side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

```
call zunmbr(vect, side, trans, m, n, k, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmbr(a, tau, c [,vect] [,side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

Given an arbitrary complex matrix C , this routine forms one of the matrix products Q^*C , Q^H*C , $C*Q$, $C*Q^H$, P^*C , P^H*C , $C*P$, or $C*P^H$, where Q and P are unitary matrices computed by a call to [cgebrd/zgebrd](#). The routine overwrites the product on C .

Input Parameters

In the descriptions below, r denotes the order of Q or P^H :

If *side* = 'L', *r* = *m*; if *side* = 'R', *r* = *n*.

vect CHARACTER*1. Must be 'Q' or 'P'.
 If *vect* = 'Q', then Q or Q^H is applied to *c*.
 If *vect* = 'P', then P or P^H is applied to *c*.

side CHARACTER*1. Must be 'L' or 'R'.
 If *side* = 'L', multipliers are applied to *c* from the left.
 If *side* = 'R', they are applied to *c* from the right.

trans CHARACTER*1. Must be 'N' or 'C'.
 If *trans* = 'N', then Q or P is applied to *c*.
 If *trans* = 'C', then Q^H or P^H is applied to *c*.

m INTEGER. The number of rows in *c*.

n INTEGER. The number of columns in *c*.

k INTEGER. One of the dimensions of *A* in ?gebrd:
 If *vect* = 'Q', the number of columns in *A*;
 If *vect* = 'P', the number of rows in *A*.
 Constraints: $m \geq 0, n \geq 0, k \geq 0$.

a, c, work COMPLEX for cunmbr
 DOUBLE COMPLEX for zunmbr.
 Arrays:
a(*lda*,*) is the array *a* as returned by ?gebrd.
 Its second dimension must be at least $\max(1, \min(r, k))$ for *vect* = 'Q', or $\max(1, r)$ for *vect* = 'P'.
c(*ldc*,*) holds the matrix *c*.
 Its second dimension must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*. Constraints:
 $lda \geq \max(1, r)$ if *vect* = 'Q';
 $lda \geq \max(1, \min(r, k))$ if *vect* = 'P'.

ldc INTEGER. The first dimension of *c*; $ldc \geq \max(1, m)$.

tau COMPLEX for cunmbr
 DOUBLE COMPLEX for zunmbr.
 Array, DIMENSION at least $\max(1, \min(r, k))$.
 For *vect* = 'Q', the array *tauq* as returned by ?gebrd.
 For *vect* = 'P', the array *taup* as returned by ?gebrd.

lwork INTEGER. The size of the *work* array.
 $lwork \geq \max(1, n)$ if *side* = 'L';
 $lwork \geq \max(1, m)$ if *side* = 'R'.
 $lwork \geq 1$ if $n=0$ or $m=0$.
 For optimum performance $lwork \geq \max(1, n*nb)$ if *side* = 'L', and $lwork \geq \max(1, m*nb)$ if *side* = 'R', where *nb* is the optimal blocksize. ($nb = 0$ if $m = 0$ or $n = 0$.)
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

Output Parameters

c Overwritten by the product Q^*C , Q^H*C , $C*Q$, $C*Q^H$, P^*C , P^H*C , C^*P , or C^*P^H , as specified by *vect*, *side*, and *trans*.

work(1) If *info* = 0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmbr` interface are the following:

a Holds the matrix *A* of size $(r, \min(nq, k))$ where
 $r = nq$, if *vect* = 'Q',
 $r = \min(nq, k)$, if *vect* = 'P',
 $nq = m$, if *side* = 'L',
 $nq = n$, if *side* = 'R',
 $k = m$, if *vect* = 'P',

	$k = n$, if $vect = 'Q'$.
tau	Holds the vector of length $\min(nq, k)$.
c	Holds the matrix C of size (m, n) .
$vect$	Must be 'Q' or 'P'. The default value is 'Q'.
$side$	Must be 'L' or 'R'. The default value is 'L'.
$trans$	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, use

$lwork = n * blocksize$ for $side = 'L'$, or

$lwork = m * blocksize$ for $side = 'R'$,

where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\epsilon) * \|C\|_2$.

The total number of floating-point operations is approximately

$8 * n * k (2 * m - k)$ if $side = 'L'$ and $m \geq k$;

$8 * m * k (2 * n - k)$ if $side = 'R'$ and $n \geq k$;

$8 * m^2 * n$ if $side = 'L'$ and $m < k$;

$8 * n^2 * m$ if $side = 'R'$ and $n < k$.

The real counterpart of this routine is [?ormbr](#).

?bdsqr

Computes the singular value decomposition of a general matrix that has been reduced to bidiagonal form.

Syntax

FORTRAN 77:

```
call sbdsqr(uplo, n, ncv, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work,
info)
call dbdsqr(uplo, n, ncv, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work,
info)
call cbdsqr(uplo, n, ncv, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work,
info)
call zbdsqr(uplo, n, ncv, nru, ncc, d, e, vt, ldvt, u, ldu, c, ldc, work,
info)
```

Fortran 95:

```
call rbdsqr(d, e [,vt] [,u] [,c] [,uplo] [,info])
call bdsqr(d, e [,vt] [,u] [,c] [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the singular values and, optionally, the right and/or left singular vectors from the [Singular Value Decomposition](#) (SVD) of a real n -by- n (upper or lower) bidiagonal matrix B using the implicit zero-shift QR algorithm. The SVD of B has the form $B = Q * S * P^H$ where S is the diagonal matrix of singular values, Q is an orthogonal matrix of left singular vectors, and P is an orthogonal matrix of right singular vectors. If left singular vectors are requested, this subroutine actually returns $U * Q$ instead of Q , and, if right singular vectors are requested, this subroutine returns $P_H * VT$ instead of P_H , for given real/complex input matrices U and VT . When U and VT are the orthogonal/unitary matrices that reduce a general matrix A to bidiagonal form: $A = U * B * VT$, as computed by [?gebrd](#), then

$$A = (U*Q)*S*(P^H*VT)$$

is the SVD of A . Optionally, the subroutine may also compute $Q_H * C$ for a given real/complex input matrix C .

See also [?lasq1](#), [?lasq2](#), [?lasq3](#), [?lasq4](#), [?lasq5](#), [?lasq6](#) used by this routine.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', B is an upper bidiagonal matrix. If <i>uplo</i> = 'L', B is a lower bidiagonal matrix.
<i>n</i>	INTEGER. The order of the matrix B ($n \geq 0$).
<i>ncvt</i>	INTEGER. The number of columns of the matrix VT , that is, the number of right singular vectors ($ncvt \geq 0$). Set <i>ncvt</i> = 0 if no right singular vectors are required.
<i>nru</i>	INTEGER. The number of rows in U , that is, the number of left singular vectors ($nru \geq 0$). Set <i>nru</i> = 0 if no left singular vectors are required.
<i>ncc</i>	INTEGER. The number of columns in the matrix C used for computing the product $Q^H * C$ ($ncc \geq 0$). Set <i>ncc</i> = 0 if no matrix C is supplied.
<i>d, e, work</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> (*) contains the diagonal elements of B . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the $(n-1)$ off-diagonal elements of B . The dimension of <i>e</i> must be at least $\max(1, n)$. <i>e</i> (n) is used for workspace. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 4*n)$.
<i>vt, u, c</i>	REAL for sbdsqr DOUBLE PRECISION for dbdsqr COMPLEX for cbdsqr DOUBLE COMPLEX for zbdsqr. Arrays: <i>vt</i> (<i>ldvt</i> ,*) contains an n -by- <i>ncvt</i> matrix VT .

The second dimension of vt must be at least $\max(1, ncvt)$.

vt is not referenced if $ncvt = 0$.

$u(ldu, *)$ contains an nru by n unit matrix U .

The second dimension of u must be at least $\max(1, n)$.

u is not referenced if $nru = 0$.

$c(ldc, *)$ contains the matrix C for computing the product $Q^H * C$.

The second dimension of c must be at least $\max(1, ncc)$.

The array is not referenced if $ncc = 0$.

$ldvt$ INTEGER. The first dimension of vt . Constraints:
 $ldvt \geq \max(1, n)$ if $ncvt > 0$;
 $ldvt \geq 1$ if $ncvt = 0$.

ldu INTEGER. The first dimension of u . Constraint:
 $ldu \geq \max(1, nru)$.

ldc INTEGER. The first dimension of c . Constraints:
 $ldc \geq \max(1, n)$ if $ncc > 0$; $ldc \geq 1$ otherwise.

Output Parameters

d On exit, if $info = 0$, overwritten by the singular values in decreasing order (see $info$).

e On exit, if $info = 0$, e is destroyed. See also $info$ below.

c Overwritten by the product $Q^H * C$.

vt On exit, this array is overwritten by $P^H * VT$.

u On exit, this array is overwritten by $U * Q$.

$info$ INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info > i$,
 if $ncvt = nru = ncc = 0$,

- $info = 1$, a split was marked by a positive value in e
- $info = 2$, the current block of z not diagonalized after $30 * n$ iterations (in the inner while loop)

- $info = 3$, termination criterion of the outer `while` loop is not met (the program created more than n unreduced blocks).

In all other cases when $ncvt = nru = ncc = 0$, the algorithm did not converge; d and e contain the elements of a bidiagonal matrix that is orthogonally similar to the input matrix B ; if $info = i$, i elements of e have not converged to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `bdsqr` interface are the following:

d	Holds the vector of length (n) .
e	Holds the vector of length (n) .
vt	Holds the matrix VT of size $(n, ncvt)$.
u	Holds the matrix U of size (nru, n) .
c	Holds the matrix C of size (n, ncc) .
$uplo$	Must be 'U' or 'L'. The default value is 'U'.
$ncvt$	If argument vt is present, then $ncvt$ is equal to the number of columns in matrix VT ; otherwise, $ncvt$ is set to zero.
nru	If argument u is present, then nru is equal to the number of rows in matrix U ; otherwise, nru is set to zero.
ncc	If argument c is present, then ncc is equal to the number of columns in matrix C ; otherwise, ncc is set to zero.

Note that two variants of Fortran 95 interface for `bdsqr` routine are needed because of an ambiguous choice between real and complex cases appear when vt , u , and c are omitted. Thus, the name `rbdsqr` is used in real cases (single or double precision), and the name `bdsqr` is used in complex cases (single or double precision).

Application Notes

Each singular value and singular vector is computed to high relative accuracy. However, the reduction to bidiagonal form (prior to calling the routine) may decrease the relative accuracy in the small singular values of the original matrix if its singular values vary widely in magnitude.

If s_i is an exact singular value of B , and σ_i is the corresponding computed value, then

$$|s_i - \sigma_i| \leq p^*(m, n) * \epsilon * \sigma_i$$

where $p(m, n)$ is a modestly increasing function of m and n , and ϵ is the machine precision.

If only singular values are computed, they are computed more accurately than when some singular vectors are also computed (that is, the function $p(m, n)$ is smaller).

If u_i is the corresponding exact left singular vector of B , and w_i is the corresponding computed left singular vector, then the angle $\theta(u_i, w_i)$ between them is bounded as follows:

$$\theta(u_i, w_i) \leq p(m, n) * \epsilon / \min_{i \neq j} (|\sigma_i - \sigma_j| / |\sigma_i + \sigma_j|).$$

Here $\min_{i \neq j} (|\sigma_i - \sigma_j| / |\sigma_i + \sigma_j|)$ is the *relative gap* between σ_i and the other singular values. A similar error bound holds for the right singular vectors.

The total number of real floating-point operations is roughly proportional to n^2 if only the singular values are computed. About $6n^2 * nru$ additional operations ($12n^2 * nru$ for complex flavors) are required to compute the left singular vectors and about $6n^2 * ncv$ operations ($12n^2 * ncv$ for complex flavors) to compute the right singular vectors.

?bdsdc

Computes the singular value decomposition of a real bidiagonal matrix using a divide and conquer method.

Syntax

FORTRAN 77:

```
call sbdsdc(uplo, compq, n, d, e, u, ldu, vt, ldvt, q, iq, work, iwork, info)
call dbdsdc(uplo, compq, n, d, e, u, ldu, vt, ldvt, q, iq, work, iwork, info)
```

Fortran 95:

```
call bdsdc(d, e [,u] [,vt] [,q] [,iq] [,uplo] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes the [Singular Value Decomposition](#) (SVD) of a real n -by- n (upper or lower) bidiagonal matrix B : $B = U \Sigma V^T$, using a divide and conquer method, where Σ is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and V are orthogonal matrices of left and right singular vectors, respectively. `?bdsdc` can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This routine uses `?lasd0`, `?lasd1`, `?lasd2`, `?lasd3`, `?lasd4`, `?lasd5`, `?lasd6`, `?lasd7`, `?lasd8`, `?lasd9`, `?lasda`, `?lasdq`, `?lasdt`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. If <code>uplo = 'U'</code> , B is an upper bidiagonal matrix. If <code>uplo = 'L'</code> , B is a lower bidiagonal matrix.
<code>compq</code>	CHARACTER*1. Must be 'N', 'P', or 'I'. If <code>compq = 'N'</code> , compute singular values only. If <code>compq = 'P'</code> , compute singular values and compute singular vectors in compact form. If <code>compq = 'I'</code> , compute singular values and singular vectors.
<code>n</code>	INTEGER. The order of the matrix B ($n \geq 0$).
<code>d, e, work</code>	REAL for <code>sbdsc</code> DOUBLE PRECISION for <code>dbdsc</code> . Arrays: <code>d(*)</code> contains the n diagonal elements of the bidiagonal matrix B . The dimension of <code>d</code> must be at least $\max(1, n)$. <code>e(*)</code> contains the off-diagonal elements of the bidiagonal matrix B . The dimension of <code>e</code> must be at least $\max(1, n)$. <code>work(*)</code> is a workspace array. The dimension of <code>work</code> must be at least: $\max(1, 4*n)$, if <code>compq = 'N'</code> ; $\max(1, 6*n)$, if <code>compq = 'P'</code> ;

	$\max(1, 3*n^2+4*n)$, if <i>compq</i> = 'I'.
<i>ldu</i>	INTEGER. The first dimension of the output array <i>u</i> ; <i>ldu</i> \geq 1. If singular vectors are desired, then <i>ldu</i> \geq $\max(1, n)$.
<i>ldvt</i>	INTEGER. The first dimension of the output array <i>vt</i> ; <i>ldvt</i> \geq 1. If singular vectors are desired, then <i>ldvt</i> \geq $\max(1, n)$.
<i>iwork</i>	INTEGER. Workspace array, dimension at least $\max(1, 8*n)$.

Output Parameters

<i>d</i>	If <i>info</i> = 0, overwritten by the singular values of <i>B</i> .
<i>e</i>	On exit, <i>e</i> is overwritten.
<i>u, vt, q</i>	REAL for sbdsdc DOUBLE PRECISION for dbdsdc. Arrays: <i>u</i> (<i>ldu</i> , *), <i>vt</i> (<i>ldvt</i> , *), <i>q</i> (*). If <i>compq</i> = 'I', then on exit <i>u</i> contains the left singular vectors of the bidiagonal matrix <i>B</i> , unless <i>info</i> \neq 0 (see <i>info</i>). For other values of <i>compq</i> , <i>u</i> is not referenced. The second dimension of <i>u</i> must be at least $\max(1, n)$. if <i>compq</i> = 'I', then on exit <i>vt</i> contains the right singular vectors of the bidiagonal matrix <i>B</i> , unless <i>info</i> \neq 0 (see <i>info</i>). For other values of <i>compq</i> , <i>vt</i> is not referenced. The second dimension of <i>vt</i> must be at least $\max(1, n)$. If <i>compq</i> = 'P', then on exit, if <i>info</i> = 0, <i>q</i> and <i>iq</i> contain the left and right singular vectors in a compact form. Specifically, <i>q</i> contains all the REAL (for sbdsdc) or DOUBLE PRECISION (for dbdsdc) data for singular vectors. For other values of <i>compq</i> , <i>q</i> is not referenced. See <i>Application notes</i> for details.
<i>iq</i>	INTEGER. Array: <i>iq</i> (*).

If `compq = 'P'`, then on exit, if `info = 0`, `q` and `iq` contain the left and right singular vectors in a compact form. Specifically, `iq` contains all the `INTEGER` data for singular vectors. For other values of `compq`, `iq` is not referenced. See *Application notes* for details.

`info`

`INTEGER`.

If `info = 0`, the execution is successful.

If `info = -i`, the *i*-th parameter had an illegal value.

If `info = i`, the algorithm failed to compute a singular value. The update process of divide and conquer failed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `bdsdc` interface are the following:

`d` Holds the vector of length *n*.

`e` Holds the vector of length *n*.

`u` Holds the matrix *U* of size (*n*,*n*).

`vt` Holds the matrix *VT* of size (*n*,*n*).

`q` Holds the vector of length (*ldq*), where

$ldq \geq n * (11 + 2 * smlsiz + 8 * \text{int}(\log_2(n / (smlsiz + 1))))$
and *smlsiz* is returned by `ilaenv` and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25).

`compq` Restored based on the presence of arguments `u`, `vt`, `q`, and `iq` as follows:

`compq = 'N'`, if none of `u`, `vt`, `q`, and `iq` are present,

`compq = 'I'`, if both `u` and `vt` are present. Arguments `u` and `vt` must either be both present or both omitted,

`compq = 'P'`, if both `q` and `iq` are present. Arguments `q` and `iq` must either be both present or both omitted.

Note that there will be an error condition if all of `u`, `vt`, `q`, and `iq` arguments are present simultaneously.

Symmetric Eigenvalue Problems

Symmetric eigenvalue problems are posed as follows: given an n -by- n real symmetric or complex Hermitian matrix A , find the *eigenvalues* λ and the corresponding *eigenvectors* z that satisfy the equation

$$Az = \lambda z \text{ (or, equivalently, } z^H A = \lambda z^H \text{)}.$$

In such eigenvalue problems, all n eigenvalues are real not only for real symmetric but also for complex Hermitian matrices A , and there exists an orthonormal system of n eigenvectors. If A is a symmetric or Hermitian positive-definite matrix, all eigenvalues are positive.

To solve a symmetric eigenvalue problem with LAPACK, you usually need to reduce the matrix to tridiagonal form and then solve the eigenvalue problem with the tridiagonal matrix obtained. LAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation $A = QTQ^H$ as well as for solving tridiagonal symmetric eigenvalue problems. These routines (for FORTRAN 77 interface) are listed in [Table 4-3](#). Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

There are different routines for symmetric eigenvalue problems, depending on whether you need all eigenvectors or only some of them or eigenvalues only, whether the matrix A is positive-definite or not, and so on.

These routines are based on three primary algorithms for computing eigenvalues and eigenvectors of symmetric problems: the divide and conquer algorithm, the QR algorithm, and bisection followed by inverse iteration. The divide and conquer algorithm is generally more efficient and is recommended for computing all eigenvalues and eigenvectors. Furthermore, to solve an eigenvalue problem using the divide and conquer algorithm, you need to call only one routine. In general, more than one routine has to be called if the QR algorithm or bisection followed by inverse iteration is used.

Decision tree in [Figure 4-2](#) will help you choose the right routine or sequence of routines for eigenvalue problems with real symmetric matrices. A similar decision tree for complex Hermitian matrices is presented in [Figure 4-3](#) .

?sytrd

Reduces a real symmetric matrix to tridiagonal form.

Syntax

FORTRAN 77:

```
call ssytrd(uplo, n, a, lda, d, e, tau, work, lwork, info)
call dsytrd(uplo, n, a, lda, d, e, tau, work, lwork, info)
```

Fortran 95:

```
call sytrd(a, tau [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q^T T Q$. The orthogonal matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with Q in this representation (see *Application Notes* below).

This routine calls [?latrd](#) to reduce a real symmetric matrix to tridiagonal form by an orthogonal similarity transformation.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. If <code>uplo = 'U'</code> , <code>a</code> stores the upper triangular part of A . If <code>uplo = 'L'</code> , <code>a</code> stores the lower triangular part of A .
<code>n</code>	INTEGER. The order of the matrix A ($n \geq 0$).
<code>a, work</code>	REAL for <code>ssytrd</code> DOUBLE PRECISION for <code>dsytrd</code> . <code>a(lda,*)</code> is an array containing either upper or lower triangular part of the matrix A , as specified by <code>uplo</code> . If <code>uplo = 'U'</code> , the leading n -by- n upper triangular part of <code>a</code> contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If <code>uplo = 'L'</code> ,

the leading n -by- n lower triangular part of a contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced.

The second dimension of a must be at least $\max(1, n)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.

lda

INTEGER. The first dimension of a ; at least $\max(1, n)$.

$lwork$

INTEGER. The size of the $work$ array ($lwork \geq n$).

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#). See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a

On exit,
 if $uplo = 'U'$, the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array tau , represent the orthogonal matrix Q as a product of elementary reflectors;
 if $uplo = 'L'$, the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array tau , represent the orthogonal matrix Q as a product of elementary reflectors.

d, e, tau

REAL for `ssytrd`
 DOUBLE PRECISION for `dsytrd`.

Arrays:

$d(*)$ contains the diagonal elements of the matrix T .

The dimension of d must be at least $\max(1, n)$.

$e(*)$ contains the off-diagonal elements of T .

The dimension of e must be at least $\max(1, n-1)$.

$tau(*)$ stores further details of the orthogonal matrix Q in the first $n-1$ elements. $tau(n)$ is used as workspace.

The dimension of tau must be at least $\max(1, n)$.

work(1) If *info*=0, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sytrd* interface are the following:

a Holds the matrix *A* of size (*n*,*n*).

tau Holds the vector of length (*n*-1).

uplo Must be 'U' or 'L'. The default value is 'U'.

Note that diagonal (*d*) and off-diagonal (*e*) elements of the matrix *T* are omitted because they are kept in the matrix *A* on exit.

Application Notes

For better performance, try using *lwork* = *n***blocksize*, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix T is exactly similar to a matrix $A+E$, where $\|E\|_2 = c(n)*\epsilon*\|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations is $(4/3)n^3$.

After calling this routine, you can call the following:

`?orgtr` to form the computed matrix Q explicitly
`?ormtr` to multiply a real matrix by Q .

The complex counterpart of this routine is `?hetrd`.

?syrd

Reduces a real symmetric matrix to tridiagonal form with Successive Bandwidth Reduction approach.

Syntax

FORTRAN 77:

```
call ssyrd(jobz, uplo, n, kd, a, lda, d, e, tau, z, ldz, work, lwork, info)
call dsyrd(jobz, uplo, n, kd, a, lda, d, e, tau, z, ldz, work, lwork, info)
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q*T*Q^T$ and optionally multiplies matrix Z by Q , or simply forms Q .

This routine reduces a full symmetric matrix to the banded symmetric form, and then to the tridiagonal symmetric form with a Successive Bandwidth Reduction approach after Prof. C.Bischof's works (see for instance, [Bischof92]). `?syrd` is functionally close to `?sytrd` routine but the tridiagonal form may differ from those obtained by `?sytrd`. Unlike `?sytrd`, the orthogonal matrix Q cannot be restored from the details of matrix A on exit.

Input Parameters

`jobz` CHARACTER*1. Must be 'N' or 'V'.

	<p>If <i>jobz</i> = 'N', then only <i>A</i> is reduced to <i>T</i>. If <i>jobz</i> = 'V', then <i>A</i> is reduced to <i>T</i> and <i>A</i> contains <i>Q</i> on exit. If <i>jobz</i> = 'U', then <i>A</i> is reduced to <i>T</i> and <i>Z</i> contains <i>Z*Q</i> on exit.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i>. If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).</p>
<i>kd</i>	<p>INTEGER. The bandwidth of the banded matrix <i>B</i> ($kd \geq 1$).</p>
<i>a, z, work</i>	<p>REAL for <i>ssyrdb</i>. DOUBLE PRECISION for <i>dsyrdb</i>. <i>a(lda,*)</i> is an array containing either upper or lower triangular part of the matrix <i>A</i>, as specified by <i>uplo</i>. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>z(ldz,*)</i>, the second dimension of <i>z</i> must be at least $\max(1, n)$. If <i>jobz</i> = 'U', then the matrix <i>z</i> is multiplied by <i>Q</i>. If <i>jobz</i> = 'N' or 'V', then <i>z</i> is not referenced. <i>work(lwork)</i> is a workspace array.</p>
<i>lda</i>	<p>INTEGER. The first dimension of <i>a</i>; at least $\max(1, n)$.</p>
<i>ldz</i>	<p>INTEGER. The first dimension of <i>z</i>; at least $\max(1, n)$. Not referenced if <i>jobz</i> = 'N'</p>
<i>lwork</i>	<p>INTEGER. The size of the <i>work</i> array ($lwork \geq (2kd+1)n+kd$). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See <i>Application Notes</i> for the suggested value of <i>lwork</i>.</p>

Output Parameters

<i>a</i>	<p>If <i>jobz</i> = 'V', then overwritten by <i>Q</i> matrix.</p>
----------	---

	If <i>jobz</i> = 'N' or 'U', then overwritten by the banded matrix <i>B</i> and details of the orthogonal matrix Q_B to reduce <i>A</i> to <i>B</i> as specified by <i>uplo</i> .
<i>z</i>	On exit, if <i>jobz</i> = 'U', then the matrix <i>z</i> is overwritten by Z^*Q . If <i>jobz</i> = 'N' or 'V', then <i>z</i> is not referenced.
<i>d, e, tau</i>	DOUBLE PRECISION. Arrays: <i>d</i> (*) contains the diagonal elements of the matrix <i>T</i> . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the off-diagonal elements of <i>T</i> . The dimension of <i>e</i> must be at least $\max(1, n-1)$. <i>tau</i> (*) stores further details of the orthogonal matrix <i>Q</i> . The dimension of <i>tau</i> must be at least $\max(1, n-kd-1)$.
<i>work</i> (1)	If <i>info</i> =0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Application Notes

For better performance, try using $lwork = n*(3*kd+3)$.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

For better performance, try using *kd* equal to 40 if $n \leq 2000$ and 64 otherwise.

Try using `?syrd` instead of `?sytrd` on large matrices obtaining only eigenvalues - when no eigenvectors are needed, especially in multi-threaded environment. `?syrd` becomes faster beginning approximately with $n = 1000$, and much faster at larger matrices with a better scalability than `?sytrd`.

Avoid applying `?syrd` for computing eigenvectors due to the two-step reduction, that is, the number of operations needed to apply orthogonal transformations to Z is doubled compared to the traditional one-step reduction. In that case it is better to apply `?sytrd` and `?ormtr/?orgtr` to obtain tridiagonal form along with the orthogonal transformation matrix Q .

?herdb

Reduces a complex Hermitian matrix to tridiagonal form with Successive Bandwidth Reduction approach.

Syntax

FORTRAN 77:

```
call cherdb(jobz, uplo, n, kd, a, lda, d, e, tau, z, ldz, work, lwork, info)
call zherdb(jobz, uplo, n, kd, a, lda, d, e, tau, z, ldz, work, lwork, info)
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine reduces a complex Hermitian matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = Q^*T^*Q^T$ and optionally multiplies matrix Z by Q , or simply forms Q .

This routine reduces a full Hermitian matrix to the banded Hermitian form, and then to the tridiagonal symmetric form with a Successive Bandwidth Reduction approach after Prof. C.Bischof's works (see for instance, [Bischof92]). `?herdb` is functionally close to `?hetrd` routine but the tridiagonal form may differ from those obtained by `?hetrd`. Unlike `?hetrd`, the orthogonal matrix Q cannot be restored from the details of matrix A on exit.

Input Parameters

jobz CHARACTER*1. Must be 'N' or 'V'.
If *jobz* = 'N', then only A is reduced to T .

	<p>If $jobz = 'V'$, then A is reduced to T and A contains Q on exit.</p> <p>If $jobz = 'U'$, then A is reduced to T and Z contains $Z*Q$ on exit.</p>
$uplo$	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If $uplo = 'U'$, a stores the upper triangular part of A.</p> <p>If $uplo = 'L'$, a stores the lower triangular part of A.</p>
n	INTEGER. The order of the matrix A ($n \geq 0$).
kd	INTEGER. The bandwidth of the banded matrix B ($kd \geq 1$).
$a, z, work$	<p>COMPLEX for <code>cherdb</code>.</p> <p>DOUBLE COMPLEX for <code>zherdb</code>.</p> <p>$a(lda,*)$ is an array containing either upper or lower triangular part of the matrix A, as specified by $uplo$.</p> <p>The second dimension of a must be at least $\max(1, n)$.</p> <p>$z(ldz,*)$, the second dimension of z must be at least $\max(1, n)$.</p> <p>If $jobz = 'U'$, then the matrix z is multiplied by Q.</p> <p>If $jobz = 'N'$ or 'V', then z is not referenced.</p> <p>$work(lwork)$ is a workspace array.</p>
lda	INTEGER. The first dimension of a ; at least $\max(1, n)$.
ldz	INTEGER. The first dimension of z ; at least $\max(1, n)$. Not referenced if $jobz = 'N'$
$lwork$	<p>INTEGER. The size of the $work$ array ($lwork \geq (2kd+1)n+kd$).</p> <p>If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by <code>xerbla</code>.</p> <p>See <i>Application Notes</i> for the suggested value of $lwork$.</p>

Output Parameters

a	<p>If $jobz = 'V'$, then overwritten by Q matrix.</p> <p>If $jobz = 'N'$ or 'U', then overwritten by the banded matrix B and details of the unitary matrix Q_B to reduce A to B as specified by $uplo$.</p>
-----	---

<i>z</i>	On exit, if <i>jobz</i> = 'U', then the matrix <i>z</i> is overwritten by Z^*Q . If <i>jobz</i> = 'N' or 'V', then <i>z</i> is not referenced.
<i>d, e</i>	COMPLEX for <i>cherdb</i> . DOUBLE COMPLEX for <i>zherdb</i> . Arrays: <i>d</i> (*) contains the diagonal elements of the matrix <i>T</i> . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the off-diagonal elements of <i>T</i> . The dimension of <i>e</i> must be at least $\max(1, n-1)$. <i>tau</i> (*) stores further details of the orthogonal matrix <i>Q</i> . The dimension of <i>tau</i> must be at least $\max(1, n-kd-1)$.
<i>tau</i>	COMPLEX for <i>cherdb</i> . DOUBLE COMPLEX for <i>zherdb</i> . Array, DIMENSION at least $\max(1, n-1)$ Stores further details of the unitary matrix Q_B . The dimension of <i>tau</i> must be at least $\max(1, n-kd-1)$.
<i>work</i> (1)	If <i>info</i> =0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Application Notes

For better performance, try using $lwork = n*(3*kd+3)$.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

For better performance, try using kd equal to 40 if $n \leq 2000$ and 64 otherwise.

Try using `?herdb` instead of `?hetrd` on large matrices obtaining only eigenvalues - when no eigenvectors are needed, especially in multi-threaded environment. `?herdb` becomes faster beginning approximately with $n = 1000$, and much faster at larger matrices with a better scalability than `?hetrd`.

Avoid applying `?herdb` for computing eigenvectors due to the two-step reduction, that is, the number of operations needed to apply orthogonal transformations to z is doubled compared to the traditional one-step reduction. In that case it is better to apply `?hetrd` and `?unmtr/?ungtr` to obtain tridiagonal form along with the unitary transformation matrix Q .

?orgtr

Generates the real orthogonal matrix Q determined by ?sytrd.

Syntax

FORTRAN 77:

```
call sorgtr(uplo, n, a, lda, tau, work, lwork, info)
call dorgtr(uplo, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orgtr(a, tau [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine explicitly generates the n -by- n orthogonal matrix Q formed by `?sytrd` when reducing a real symmetric matrix A to tridiagonal form: $A = Q^T T Q$. Use this routine after a call to `?sytrd`.

Input Parameters

$uplo$ CHARACTER*1. Must be 'U' or 'L'.

	Use the same <i>uplo</i> as supplied to <code>?sytrd</code> .
<i>n</i>	INTEGER. The order of the matrix <i>Q</i> ($n \geq 0$).
<i>a</i> , <i>tau</i> , <i>work</i>	REAL for <code>sorgtr</code> DOUBLE PRECISION for <code>dorgtr</code> . Arrays: <i>a</i> (<i>lda</i> ,*) is the array <i>a</i> as returned by <code>?sytrd</code> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>tau</i> (*) is the array <i>tau</i> as returned by <code>?sytrd</code> . The dimension of <i>tau</i> must be at least $\max(1, n-1)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array ($lwork \geq n$). If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	Overwritten by the orthogonal matrix <i>Q</i> .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orgtr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>tau</i>	Holds the vector of length (<i>n</i> -1).

`uplo` Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For better performance, try using $lwork = (n-1)*blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix *Q* differs from an exactly orthogonal matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of floating-point operations is $(4/3)n^3$.

The complex counterpart of this routine is [?ungtr](#).

?ormtr

Multiplies a real matrix by the real orthogonal matrix Q determined by ?sytrd.

Syntax

FORTRAN 77:

```
call sormtr(side, uplo, trans, m, n, a, lda, tau, c, ldc, work, lwork, info)
call dormtr(side, uplo, trans, m, n, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call ormtr(a, tau, c [,side] [,uplo] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a real matrix c by q or q^T , where q is the orthogonal matrix q formed by `?sytrd` when reducing a real symmetric matrix A to tridiagonal form: $A = Q^T * Q$. Use this routine after a call to `?sytrd`.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products $Q * C$, $Q^T * C$, $C * Q$, or $C * Q^T$ (overwriting the result on c).

Input Parameters

In the descriptions below, r denotes the order of q :

If `side = 'L'`, $r = m$; if `side = 'R'`, $r = n$.

<code>side</code>	CHARACTER*1. Must be either 'L' or 'R'. If <code>side = 'L'</code> , q or q^T is applied to c from the left. If <code>side = 'R'</code> , q or q^T is applied to c from the right.
<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Use the same <code>uplo</code> as supplied to <code>?sytrd</code> .
<code>trans</code>	CHARACTER*1. Must be either 'N' or 'T'. If <code>trans = 'N'</code> , the routine multiplies c by q . If <code>trans = 'T'</code> , the routine multiplies c by q^T .
<code>m</code>	INTEGER. The number of rows in the matrix c ($m \geq 0$).
<code>n</code>	INTEGER. The number of columns in c ($n \geq 0$).
<code>a, c, tau, work</code>	REAL for <code>sormtr</code> DOUBLE PRECISION for <code>dormtr</code> <code>a(lda,*)</code> and <code>tau</code> are the arrays returned by <code>?sytrd</code> . The second dimension of <code>a</code> must be at least $\max(1, r)$. The dimension of <code>tau</code> must be at least $\max(1, r-1)$. <code>c(ldc,*)</code> contains the matrix c . The second dimension of <code>c</code> must be at least $\max(1, n)$ <code>work</code> is a workspace array, its dimension $\max(1, lwork)$.

<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, r)$.
<i>ldc</i>	INTEGER. The first dimension of <i>c</i> ; $ldc \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints: $lwork \geq \max(1, n)$ if <i>side</i> = 'L'; $lwork \geq \max(1, m)$ if <i>side</i> = 'R'. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>c</i>	Overwritten by the product $Q^T C$, $Q^T * C$, $C^T Q$, or $C * Q^T$ (as specified by <i>side</i> and <i>trans</i>).
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormtr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>r</i> , <i>r</i>). $r = m$ if <i>side</i> = 'L'. $r = n$ if <i>side</i> = 'R'.
<i>tau</i>	Holds the vector of length (<i>r</i> -1).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

trans Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n * blocksize$ for $side = 'L'$, or $lwork = m * blocksize$ for $side = 'R'$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed product differs from the exact product by a matrix E such that $\|E\|^2 = O(\epsilon) * \|C\|^2$.

The total number of floating-point operations is approximately $2 * m^2 * n$, if $side = 'L'$, or $2 * n^2 * m$, if $side = 'R'$.

The complex counterpart of this routine is [?unmtr](#).

?hetrd

Reduces a complex Hermitian matrix to tridiagonal form.

Syntax

FORTRAN 77:

```
call chetrd(uplo, n, a, lda, d, e, tau, work, lwork, info)
call zhetrd(uplo, n, a, lda, d, e, tau, work, lwork, info)
```

Fortran 95:

```
call hetrd(a, tau [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reduces a complex Hermitian matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = Q^*T^*Q^H$. The unitary matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided to work with Q in this representation. (They are described later in this section.)

This routine calls `?latrd` to reduce a complex Hermitian matrix A to Hermitian tridiagonal form by a unitary similarity transformation.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>a, work</i>	COMPLEX for <code>chetrd</code> DOUBLE COMPLEX for <code>zhetr</code> . <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the matrix A , as specified by <i>uplo</i> . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of <i>a</i> contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of <i>a</i> contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced. The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array ($lwork \geq n$).

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>a</i>	On exit, if <i>uplo</i> = 'U', the diagonal and first superdiagonal of <i>A</i> are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the diagonal and first subdiagonal of <i>A</i> are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements below the first subdiagonal, with the array <i>tau</i> , represent the orthogonal matrix <i>Q</i> as a product of elementary reflectors.
<i>d, e</i>	REAL for <code>chetrd</code> DOUBLE PRECISION for <code>zhetrd</code> . Arrays: <i>d</i> (*) contains the diagonal elements of the matrix <i>T</i> . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the off-diagonal elements of <i>T</i> . The dimension of <i>e</i> must be at least $\max(1, n-1)$.
<i>tau</i>	COMPLEX for <code>chetrd</code> DOUBLE COMPLEX for <code>zhetrd</code> . Array, DIMENSION at least $\max(1, n-1)$. Stores further details of the unitary matrix <i>Q</i> .
<i>work</i> (1)	If <i>info</i> = 0, on exit <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hetrd` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>tau</code>	Holds the vector of length $(n-1)$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Note that diagonal (d) and off-diagonal (e) elements of the matrix T are omitted because they are kept in the matrix A on exit.

Application Notes

For better performance, try using `lwork = n*blocksize`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix T is exactly similar to a matrix $A + E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3)n^3$.

After calling this routine, you can call the following:

`?ungtr` to form the computed matrix Q explicitly

`?unmtr` to multiply a complex matrix by Q .

The real counterpart of this routine is `?sytrd`.

?ungtr

Generates the complex unitary matrix Q determined by ?hetrd.

Syntax

FORTRAN 77:

```
call cungr( uplo, n, a, lda, tau, work, lwork, info)
call zungtr( uplo, n, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call ungr( a, tau [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine explicitly generates the n -by- n unitary matrix Q formed by `?hetrd` when reducing a complex Hermitian matrix A to tridiagonal form: $A = Q^T Q^H$. Use this routine after a call to `?hetrd`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Use the same <code>uplo</code> as supplied to <code>?hetrd</code> .
<code>n</code>	INTEGER. The order of the matrix Q ($n \geq 0$).
<code>a, tau, work</code>	COMPLEX for <code>cungr</code> DOUBLE COMPLEX for <code>zungtr</code> . Arrays: <code>a(lda,*)</code> is the array <code>a</code> as returned by <code>?hetrd</code> . The second dimension of <code>a</code> must be at least $\max(1, n)$. <code>tau(*)</code> is the array <code>tau</code> as returned by <code>?hetrd</code> . The dimension of <code>tau</code> must be at least $\max(1, n-1)$. <code>work</code> is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

lwork INTEGER. The size of the *work* array ($lwork \geq n$).
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a Overwritten by the unitary matrix *Q*.

work(1) If $info = 0$, on exit *work(1)* contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ungtr` interface are the following:

a Holds the matrix *A* of size (n, n) .

tau Holds the vector of length $(n-1)$.

uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For better performance, try using $lwork = (n-1) * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix *Q* differs from an exactly unitary matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3)n^3$.

The real counterpart of this routine is [?orgtr](#).

?unmtr

Multiplies a complex matrix by the complex unitary matrix Q determined by ?hetrd.

Syntax

FORTRAN 77:

```
call cunmtr(side, uplo, trans, m, n, a, lda, tau, c, ldc, work, lwork, info)
call zunmtr(side, uplo, trans, m, n, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmtr(a, tau, c [,side] [,uplo] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a complex matrix *c* by *Q* or Q^H , where *Q* is the unitary matrix *Q* formed by [?hetrd](#) when reducing a complex Hermitian matrix *A* to tridiagonal form: $A = Q^*T^*Q^H$. Use this routine after a call to [?hetrd](#).

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products Q^*C , $Q^H * C$, $C * Q$, or $C * Q^H$ (overwriting the result on *C*).

Input Parameters

In the descriptions below, *r* denotes the order of *Q*:

If *side* = 'L', *r* = *m*; if *side* = 'R', *r* = *n*.

<i>side</i>	CHARACTER*1. Must be either 'L' or 'R'. If <i>side</i> = 'L', <i>Q</i> or Q^H is applied to <i>C</i> from the left. If <i>side</i> = 'R', <i>Q</i> or Q^H is applied to <i>C</i> from the right.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to ?hetrd.
<i>trans</i>	CHARACTER*1. Must be either 'N' or 'T'. If <i>trans</i> = 'N', the routine multiplies <i>C</i> by <i>Q</i> . If <i>trans</i> = 'T', the routine multiplies <i>C</i> by Q^H .
<i>m</i>	INTEGER. The number of rows in the matrix <i>C</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in <i>C</i> ($n \geq 0$).
<i>a</i> , <i>c</i> , <i>tau</i> , <i>work</i>	COMPLEX for cunmtr DOUBLE COMPLEX for zunmtr. <i>a</i> (<i>lda</i> ,*) and <i>tau</i> are the arrays returned by ?hetrd. The second dimension of <i>a</i> must be at least $\max(1, r)$. The dimension of <i>tau</i> must be at least $\max(1, r-1)$. <i>c</i> (<i>ldc</i> ,*) contains the matrix <i>C</i> . The second dimension of <i>c</i> must be at least $\max(1, n)$ <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; $lda \geq \max(1, r)$.
<i>ldc</i>	INTEGER. The first dimension of <i>c</i> ; $ldc \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. Constraints: $lwork \geq \max(1, n)$ if <i>side</i> = 'L'; $lwork \geq \max(1, m)$ if <i>side</i> = 'R'.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`. See *Application Notes* for the suggested value of $lwork$.

Output Parameters

c	Overwritten by the product Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (as specified by $side$ and $trans$).
$work(1)$	If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmtr` interface are the following:

a	Holds the matrix A of size (r, r) . $r = m$ if $side = 'L'$. $r = n$ if $side = 'R'$.
tau	Holds the vector of length $(r-1)$.
c	Holds the matrix C of size (m, n) .
$side$	Must be 'L' or 'R'. The default value is 'L'.
$uplo$	Must be 'U' or 'L'. The default value is 'U'.
$trans$	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, try using $lwork = n*blocksize$ (for $side = 'L'$) or $lwork = m*blocksize$ (for $side = 'R'$) where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1 , then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\varepsilon) * \|C\|_2$, where ε is the machine precision.

The total number of floating-point operations is approximately $8*m^2*n$ if $side = 'L'$ or $8*n^2*m$ if $side = 'R'$.

The real counterpart of this routine is [?ormtr](#).

?sptrd

Reduces a real symmetric matrix to tridiagonal form using packed storage.

Syntax

FORTRAN 77:

```
call ssptrd(uplo, n, ap, d, e, tau, info)
```

```
call dsptrd(uplo, n, ap, d, e, tau, info)
```

Fortran 95:

```
call sptrd(ap, tau [,uplo] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine reduces a packed real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q^*T^*Q^T$. The orthogonal matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with Q in this representation (see *Application Notes* below).

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', *ap* stores the packed upper triangle of A .
 If *uplo* = 'L', *ap* stores the packed lower triangle of A .

n INTEGER. The order of the matrix A ($n \geq 0$).

ap REAL for *ssptrd*
 DOUBLE PRECISION for *dsptrd*.
 Array, DIMENSION at least $\max(1, n(n+1)/2)$. Contains either upper or lower triangle of A (as specified by *uplo*) in packed form.

Output Parameters

ap Overwritten by the tridiagonal matrix T and details of the orthogonal matrix Q , as specified by *uplo*.

d, *e*, *tau* REAL for *ssptrd*
 DOUBLE PRECISION for *dsptrd*.
 Arrays:
d(*) contains the diagonal elements of the matrix T .
 The dimension of *d* must be at least $\max(1, n)$.
e(*) contains the off-diagonal elements of T .
 The dimension of *e* must be at least $\max(1, n-1)$.
tau(*) stores further details of the matrix Q .
 The dimension of *tau* must be at least $\max(1, n-1)$.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sptrd` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>tau</code>	Holds the vector with the number of elements $n-1$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Note that diagonal (d) and off-diagonal (e) elements of the matrix T are omitted because they are kept in the matrix A on exit.

Application Notes

The computed matrix T is exactly similar to a matrix $A+E$, where $\|E\|_2 = c(n)*\epsilon*\|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision. The approximate number of floating-point operations is $(4/3)n^3$.

After calling this routine, you can call the following:

<code>?opgtr</code>	to form the computed matrix Q explicitly
<code>?opmtr</code>	to multiply a real matrix by Q .

The complex counterpart of this routine is `?hptrd`.

?opgtr

Generates the real orthogonal matrix Q determined by `?sptrd`.

Syntax

FORTRAN 77:

```
call sopgtr(uplo, n, ap, tau, q, ldq, work, info)
call dopgtr(uplo, n, ap, tau, q, ldq, work, info)
```

Fortran 95:

```
call opgtr(ap, tau, q [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine explicitly generates the n -by- n orthogonal matrix Q formed by `?sptrd` when reducing a packed real symmetric matrix A to tridiagonal form: $A = Q^T Q$. Use this routine after a call to `?sptrd`.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Use the same <code>uplo</code> as supplied to <code>?sptrd</code> .
<code>n</code>	INTEGER. The order of the matrix Q ($n \geq 0$).
<code>ap, tau</code>	REAL for <code>sopgtr</code> DOUBLE PRECISION for <code>dopgtr</code> . Arrays <code>ap</code> and <code>tau</code> , as returned by <code>?sptrd</code> . The dimension of <code>ap</code> must be at least $\max(1, n(n+1)/2)$. The dimension of <code>tau</code> must be at least $\max(1, n-1)$.
<code>ldq</code>	INTEGER. The first dimension of the output array <code>q</code> ; at least $\max(1, n)$.
<code>work</code>	REAL for <code>sopgtr</code> DOUBLE PRECISION for <code>dopgtr</code> . Workspace array, DIMENSION at least $\max(1, n-1)$.

Output Parameters

<code>q</code>	REAL for <code>sopgtr</code> DOUBLE PRECISION for <code>dopgtr</code> . Array, DIMENSION (<code>ldq</code> ,*). Contains the computed matrix Q . The second dimension of <code>q</code> must be at least $\max(1, n)$.
<code>info</code>	INTEGER. If <code>info</code> = 0, the execution is successful. If <code>info</code> = $-i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `opgtr` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
-----------------	---

<i>tau</i>	Holds the vector with the number of elements $n - 1$.
<i>q</i>	Holds the matrix Q of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\| |E| \|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of floating-point operations is $(4/3)n^3$.

The complex counterpart of this routine is `?upgtr`.

?opmtr

Multiplies a real matrix by the real orthogonal matrix Q determined by ?sptrd.

Syntax

FORTRAN 77:

```
call sopmtr(side, uplo, trans, m, n, ap, tau, c, ldc, work, info)
call dopmtr(side, uplo, trans, m, n, ap, tau, c, ldc, work, info)
```

Fortran 95:

```
call opmtr(ap, tau, c [,side] [,uplo] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a real matrix C by Q or Q^T , where Q is the orthogonal matrix Q formed by `?sptrd` when reducing a packed real symmetric matrix A to tridiagonal form: $A = Q^T A Q$. Use this routine after a call to `?sptrd`.

Depending on the parameters *side* and *trans*, the routine can form one of the matrix products $Q^T C$, $Q^T C$, $C^T Q$, or $C^T Q^T$ (overwriting the result on C).

Input Parameters

In the descriptions below, r denotes the order of Q :

If *side* = 'L', *r* = *m*; if *side* = 'R', *r* = *n*.

side CHARACTER*1. Must be either 'L' or 'R'.
 If *side* = 'L', Q or Q^T is applied to c from the left.
 If *side* = 'R', Q or Q^T is applied to c from the right.

uplo CHARACTER*1. Must be 'U' or 'L'.
 Use the same *uplo* as supplied to ?sptrd.

trans CHARACTER*1. Must be either 'N' or 'T'.
 If *trans* = 'N', the routine multiplies c by Q .
 If *trans* = 'T', the routine multiplies c by Q^T .

m INTEGER. The number of rows in the matrix c ($m \geq 0$).

n INTEGER. The number of columns in c ($n \geq 0$).

ap, *tau*, *c*, *work* REAL for sopmtr
 DOUBLE PRECISION for dopmtr.
ap and *tau* are the arrays returned by ?sptrd.
 The dimension of *ap* must be at least $\max(1, r(r+1)/2)$.
 The dimension of *tau* must be at least $\max(1, r-1)$.
c(ldc,)* contains the matrix c .
 The second dimension of *c* must be at least $\max(1, n)$.
work()* is a workspace array.
 The dimension of *work* must be at least
 $\max(1, n)$ if *side* = 'L';
 $\max(1, m)$ if *side* = 'R'.

ldc INTEGER. The first dimension of *c*; $ldc \geq \max(1, n)$.

Output Parameters

c Overwritten by the product $Q^T C$, $Q^T C$, $C^T Q$, or $C^T Q^T$ (as specified by *side* and *trans*).

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `opmtr` interface are the following:

<code>ap</code>	Holds the array A of size $(r*(r+1)/2)$, where $r = m$ if <code>side = 'L'</code> . $r = n$ if <code>side = 'R'</code> .
<code>tau</code>	Holds the vector with the number of elements $r - 1$.
<code>c</code>	Holds the matrix C of size (m, n) .
<code>side</code>	Must be 'L' or 'R'. The default value is 'L'.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>trans</code>	Must be 'N', 'C', or 'T'. The default value is 'N'.

Application Notes

The computed product differs from the exact product by a matrix E such that $\|E\|_2 = O(\epsilon) \|C\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $2*m^2*n$ if `side = 'L'`, or $2*n^2*m$ if `side = 'R'`.

The complex counterpart of this routine is `?upmtr`.

?hptrd

Reduces a complex Hermitian matrix to tridiagonal form using packed storage.

Syntax

FORTRAN 77:

```
call chptrd(uplo, n, ap, d, e, tau, info)
call zhptrd(uplo, n, ap, d, e, tau, info)
```

Fortran 95:

```
call hptrd(ap, tau [,uplo] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine reduces a packed complex Hermitian matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = Q^*T^*Q^H$. The unitary matrix Q is not formed explicitly but is represented as a product of $n-1$ elementary reflectors. Routines are provided for working with Q in this representation (see *Application Notes* below).

Input Parameters

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', *ap* stores the packed upper triangle of A .
 If *uplo* = 'L', *ap* stores the packed lower triangle of A .

n INTEGER. The order of the matrix A ($n \geq 0$).

ap COMPLEX for `chptrd`
 DOUBLE COMPLEX for `zhptrd`.
 Array, DIMENSION at least $\max(1, n(n+1)/2)$. Contains either upper or lower triangle of A (as specified by *uplo*) in packed form.

Output Parameters

ap Overwritten by the tridiagonal matrix T and details of the orthogonal matrix Q , as specified by *uplo*.

d, e REAL for `chptrd`
 DOUBLE PRECISION for `zhptrd`.
 Arrays:
d(*) contains the diagonal elements of the matrix T .
 The dimension of *d* must be at least $\max(1, n)$.
e(*) contains the off-diagonal elements of T .
 The dimension of *e* must be at least $\max(1, n-1)$.

tau COMPLEX for `chptrd`
 DOUBLE COMPLEX for `zhptrd`.
 Arrays, DIMENSION at least $\max(1, n-1)$. Contains further details of the orthogonal matrix Q .

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = $-i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hptrd` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>tau</code>	Holds the vector with the number of elements $n - 1$.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Note that diagonal (d) and off-diagonal (e) elements of the matrix T are omitted because they are kept in the matrix A on exit.

Application Notes

The computed matrix T is exactly similar to a matrix $A + E$, where $\|E\|_2 = c(n)*\epsilon*\|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3)n^3$.

After calling this routine, you can call the following:

<code>?upgtr</code>	to form the computed matrix Q explicitly
<code>?upmtr</code>	to multiply a complex matrix by Q .

The real counterpart of this routine is `?sptrd`.

?upgtr

Generates the complex unitary matrix Q determined by ?hptrd.

Syntax

FORTRAN 77:

```
call cupgtr(uplo, n, ap, tau, q, ldq, work, info)
call zupgtr(uplo, n, ap, tau, q, ldq, work, info)
```

Fortran 95:

```
call upgtr(ap, tau, q [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine explicitly generates the n -by- n unitary matrix Q formed by `?hptrd` when reducing a packed complex Hermitian matrix A to tridiagonal form: $A = Q^*T^*Q^H$. Use this routine after a call to `?hptrd`.

Input Parameters

<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. Use the same <i>uplo</i> as supplied to <code>?hptrd</code> .
<i>n</i>	INTEGER. The order of the matrix Q ($n \geq 0$).
<i>ap, tau</i>	COMPLEX for <code>cupgtr</code> DOUBLE COMPLEX for <code>zupgtr</code> . Arrays <i>ap</i> and <i>tau</i> , as returned by <code>?hptrd</code> . The dimension of <i>ap</i> must be at least $\max(1, n(n+1)/2)$. The dimension of <i>tau</i> must be at least $\max(1, n-1)$.
<i>ldq</i>	INTEGER. The first dimension of the output array <i>q</i> ; at least $\max(1, n)$.
<i>work</i>	COMPLEX for <code>cupgtr</code> DOUBLE COMPLEX for <code>zupgtr</code> . Workspace array, DIMENSION at least $\max(1, n-1)$.

Output Parameters

<i>q</i>	COMPLEX for <code>cupgtr</code> DOUBLE COMPLEX for <code>zupgtr</code> . Array, DIMENSION (<i>ldq</i> ,*). Contains the computed matrix Q . The second dimension of <i>q</i> must be at least $\max(1, n)$.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `upgtr` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.

The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of floating-point operations is $(16/3)n^3$.

The real counterpart of this routine is [?opgtr](#).

?upmtr

Multiplies a complex matrix by the unitary matrix Q determined by ?hptrd.

Syntax

FORTRAN 77:

```
call cupmtr(side, uplo, trans, m, n, ap, tau, c, ldc, work, info)
call zupmtr(side, uplo, trans, m, n, ap, tau, c, ldc, work, info)
```

Fortran 95:

```
call upmtr(ap, tau, c [,side] [,uplo] [,trans] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine multiplies a complex matrix C by Q or Q^H , where Q is the unitary matrix formed by `?hptrd` when reducing a packed complex Hermitian matrix A to tridiagonal form: $A = Q^*T^*Q^H$. Use this routine after a call to `?hptrd`.

Depending on the parameters `side` and `trans`, the routine can form one of the matrix products Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (overwriting the result on C).

Input Parameters

In the descriptions below, r denotes the order of Q :

If `side = 'L'`, $r = m$; if `side = 'R'`, $r = n$.

<code>side</code>	CHARACTER*1. Must be either 'L' or 'R'. If <code>side = 'L'</code> , Q or Q^H is applied to C from the left. If <code>side = 'R'</code> , Q or Q^H is applied to C from the right.
<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. Use the same <code>uplo</code> as supplied to <code>?hptrd</code> .
<code>trans</code>	CHARACTER*1. Must be either 'N' or 'T'. If <code>trans = 'N'</code> , the routine multiplies C by Q . If <code>trans = 'T'</code> , the routine multiplies C by Q^H .
<code>m</code>	INTEGER. The number of rows in the matrix C ($m \geq 0$).
<code>n</code>	INTEGER. The number of columns in C ($n \geq 0$).
<code>ap, tau, c,</code>	COMPLEX for <code>cupmtr</code> DOUBLE COMPLEX for <code>zupmtr</code> . <code>ap</code> and <code>tau</code> are the arrays returned by <code>?hptrd</code> . The dimension of <code>ap</code> must be at least $\max(1, r(r+1)/2)$. The dimension of <code>tau</code> must be at least $\max(1, r-1)$. <code>c(ldc,*)</code> contains the matrix C . The second dimension of <code>c</code> must be at least $\max(1, n)$. <code>work(*)</code> is a workspace array. The dimension of <code>work</code> must be at least $\max(1, n)$ if <code>side = 'L'</code> ; $\max(1, m)$ if <code>side = 'R'</code> .
<code>ldc</code>	INTEGER. The first dimension of <code>c</code> ; $ldc \geq \max(1, n)$.

Output Parameters

<i>c</i>	Overwritten by the product Q^*C , Q^H*C , $C*Q$, or $C*Q^H$ (as specified by <i>side</i> and <i>trans</i>).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `upmtr` interface are the following:

<i>ap</i>	Holds the array <i>A</i> of size $(r*(r+1)/2)$, where $r = m$ if <i>side</i> = 'L'. $r = n$ if <i>side</i> = 'R'.
<i>tau</i>	Holds the vector with the number of elements $n - 1$.
<i>c</i>	Holds the matrix <i>C</i> of size (m, n) .
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>trans</i>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

The computed product differs from the exact product by a matrix *E* such that $\|E\|_2 = O(\epsilon) * \|C\|_2$, where ϵ is the machine precision.

The total number of floating-point operations is approximately $8*m^2*n$ if *side* = 'L' or $8*n^2*m$ if *side* = 'R'.

The real counterpart of this routine is [?opmtr](#).

?sbtrd

Reduces a real symmetric band matrix to tridiagonal form.

Syntax

FORTRAN 77:

```
call ssbtrd(vect, uplo, n, kd, ab, ldab, d, e, q, ldq, work, info)
call dsbtrd(vect, uplo, n, kd, ab, ldab, d, e, q, ldq, work, info)
```

Fortran 95:

```
call sbtrd(ab[, q] [,vect] [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reduces a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: $A = Q^T T Q^T$. The orthogonal matrix Q is determined as a product of Givens rotations.

If required, the routine can also form the matrix Q explicitly.

Input Parameters

<i>vect</i>	CHARACTER*1. Must be 'V' or 'N'. If <i>vect</i> = 'V', the routine returns the explicit matrix Q . If <i>vect</i> = 'N', the routine does not return Q .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in A ($kd \geq 0$).
<i>ab, work</i>	REAL for <code>ssbtrd</code> DOUBLE PRECISION for <code>dsbtrd</code> .

$ab(ldab,*)$ is an array containing either upper or lower triangular part of the matrix A (as specified by $uplo$) in band storage format.

The second dimension of ab must be at least $\max(1, n)$.

$work(*)$ is a workspace array.

The dimension of $work$ must be at least $\max(1, n)$.

$ldab$

INTEGER. The first dimension of ab ; at least $kd+1$.

ldq

INTEGER. The first dimension of q . Constraints:

$ldq \geq \max(1, n)$ if $vect = 'V'$;

$ldq \geq 1$ if $vect = 'N'$.

Output Parameters

ab

On exit, the diagonal elements of the array ab are overwritten by the diagonal elements of the tridiagonal matrix T . If $kd > 0$, the elements on the first superdiagonal (if $uplo = 'U'$) or the first subdiagonal (if $uplo = 'L'$) are overwritten by the off-diagonal elements of T . The rest of ab is overwritten by values generated during the reduction.

d, e, q

REAL for `ssbtrd`

DOUBLE PRECISION for `dsbtrd`.

Arrays:

$d(*)$ contains the diagonal elements of the matrix T .

The dimension of d must be at least $\max(1, n)$.

$e(*)$ contains the off-diagonal elements of T .

The dimension of e must be at least $\max(1, n-1)$.

$q(ldq,*)$ is not referenced if $vect = 'N'$.

If $vect = 'V'$, q contains the n -by- n matrix Q .

The second dimension of q must be:

at least $\max(1, n)$ if $vect = 'V'$;

at least 1 if $vect = 'N'$.

$info$

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sbtrd` interface are the following:

<code>ab</code>	Holds the array A of size $(kd+1, n)$.
<code>q</code>	Holds the matrix Q of size (n, n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>vect</code>	If omitted, this argument is restored based on the presence of argument q as follows: $vect = 'V'$, if q is present, $vect = 'N'$, if q is omitted. If present, $vect$ must be equal to 'V' or 'U' and the argument q must also be present. Note that there will be an error condition if $vect$ is present and q omitted.

Note that diagonal (d) and off-diagonal (e) elements of the matrix T are omitted because they are kept in the matrix A on exit.

Application Notes

The computed matrix T is exactly similar to a matrix $A+E$, where $\|E\|_2 = c(n)*\epsilon*\|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision. The computed matrix Q differs from an exactly orthogonal matrix by a matrix E such that $\|E\|_2 = O(\epsilon)$.

The total number of floating-point operations is approximately $6n^2*kd$ if $vect = 'N'$, with $3n^3*(kd-1)/kd$ additional operations if $vect = 'V'$.

The complex counterpart of this routine is [?hbtrd](#).

?hbtrd

Reduces a complex Hermitian band matrix to tridiagonal form.

Syntax

FORTRAN 77:

```
call chbtrd(vect, uplo, n, kd, ab, ldab, d, e, q, ldq, work, info)
call zhbtrd(vect, uplo, n, kd, ab, ldab, d, e, q, ldq, work, info)
```

Fortran 95:

```
call hbtrd(ab [, q] [,vect] [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reduces a complex Hermitian band matrix A to symmetric tridiagonal form T by a unitary similarity transformation: $A = Q^*T^*Q^H$. The unitary matrix Q is determined as a product of Givens rotations.

If required, the routine can also form the matrix Q explicitly.

Input Parameters

<i>vect</i>	CHARACTER*1. Must be 'V' or 'N'. If <i>vect</i> = 'V', the routine returns the explicit matrix Q . If <i>vect</i> = 'N', the routine does not return Q .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>kd</i>	INTEGER. The number of super- or sub-diagonals in A ($kd \geq 0$).
<i>ab, work</i>	COMPLEX for <code>chbtrd</code> DOUBLE COMPLEX for <code>zhbtrd</code> . <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the matrix A (as specified by <i>uplo</i>) in band storage format. The second dimension of <i>ab</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, n)$.
<i>ldab</i>	INTEGER. The first dimension of <i>ab</i> ; at least $kd+1$.
<i>ldq</i>	INTEGER. The first dimension of <i>q</i> . Constraints: $ldq \geq \max(1, n)$ if <i>vect</i> = 'V'; $ldq \geq 1$ if <i>vect</i> = 'N'.

Output Parameters

<i>ab</i>	On exit, the diagonal elements of the array <i>ab</i> are overwritten by the diagonal elements of the tridiagonal matrix <i>T</i> . If $kd > 0$, the elements on the first superdiagonal (if <i>uplo</i> = 'U') or the first subdiagonal (if <i>uplo</i> = 'L') are overwritten by the off-diagonal elements of <i>T</i> . The rest of <i>ab</i> is overwritten by values generated during the reduction.
<i>d, e</i>	REAL for chbtrd DOUBLE PRECISION for zhbtrd. Arrays: <i>d</i> (*) contains the diagonal elements of the matrix <i>T</i> . The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the off-diagonal elements of <i>T</i> . The dimension of <i>e</i> must be at least $\max(1, n-1)$.
<i>q</i>	COMPLEX for chbtrd DOUBLE COMPLEX for zhbtrd. Array, DIMENSION (<i>ldq</i> ,*). If <i>vect</i> = 'N', <i>q</i> is not referenced. If <i>vect</i> = 'V', <i>q</i> contains the <i>n</i> -by- <i>n</i> matrix <i>Q</i> . The second dimension of <i>q</i> must be: at least $\max(1, n)$ if <i>vect</i> = 'V'; at least 1 if <i>vect</i> = 'N'.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hbtrd` interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size $(kd+1, n)$.
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

vect

If omitted, this argument is restored based on the presence of argument *q* as follows: *vect* = 'V', if *q* is present, *vect* = 'N', if *q* is omitted. If present, *vect* must be equal to 'V' or 'U' and the argument *q* must also be present. Note that there will be an error condition if *vect* is present and *q* omitted.

Note that diagonal (*d*) and off-diagonal (*e*) elements of the matrix *T* are omitted because they are kept in the matrix *A* on exit.

Application Notes

The computed matrix *T* is exactly similar to a matrix $A + E$, where $\|E\|_2 = c(n) * \epsilon * \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision. The computed matrix *Q* differs from an exactly unitary matrix by a matrix *E* such that $\|E\|_2 = O(\epsilon)$.

The total number of floating-point operations is approximately $20n^2 * kd$ if *vect* = 'N', with $10n^3 * (kd - 1) / kd$ additional operations if *vect* = 'V'.

The real counterpart of this routine is [?sbtrd](#).

?sterf

Computes all eigenvalues of a real symmetric tridiagonal matrix using QR algorithm.

Syntax

FORTRAN 77:

```
call ssterf(n, d, e, info)
```

```
call dsterf(n, d, e, info)
```

Fortran 95:

```
call sterf(d, e [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes all the eigenvalues of a real symmetric tridiagonal matrix T (which can be obtained by reducing a symmetric or Hermitian matrix to tridiagonal form). The routine uses a square-root-free variant of the QR algorithm.

If you need not only the eigenvalues but also the eigenvectors, call [?stegr](#).

Input Parameters

n INTEGER. The order of the matrix T ($n \geq 0$).

d, e REAL for `ssterf`
DOUBLE PRECISION for `dsterf`.

Arrays:
 $d(*)$ contains the diagonal elements of T .
 The dimension of d must be at least $\max(1, n)$.
 $e(*)$ contains the off-diagonal elements of T .
 The dimension of e must be at least $\max(1, n-1)$.

Output Parameters

d The n eigenvalues in ascending order, unless $info > 0$.
See also $info$.

e On exit, the array is overwritten; see $info$.

$info$ INTEGER.
 If $info = 0$, the execution is successful.
 If $info = i$, the algorithm failed to find all the eigenvalues after $30n$ iterations:
 i off-diagonal elements have not converged to zero. On exit, d and e contain, respectively, the diagonal and off-diagonal elements of a tridiagonal matrix orthogonally similar to T .
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sterf` interface are the following:

d Holds the vector of length n .

e Holds the vector of length $(n-1)$.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\varepsilon) * \|T\|_2$, where ε is the machine precision.

If λ_i is an exact eigenvalue, and m_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \varepsilon * \|T\|_2$$

where $c(n)$ is a modestly increasing function of n .

The total number of floating-point operations depends on how rapidly the algorithm converges. Typically, it is about $14n^2$.

?steqr

Computes all eigenvalues and eigenvectors of a symmetric or Hermitian matrix reduced to tridiagonal form (QR algorithm).

Syntax

FORTRAN 77:

```
call ssteqr(compz, n, d, e, z, ldz, work, info)
call dsteqr(compz, n, d, e, z, ldz, work, info)
call csteqr(compz, n, d, e, z, ldz, work, info)
call zsteqr(compz, n, d, e, z, ldz, work, info)
```

Fortran 95:

```
call rsteqr(d, e [,z] [,compz] [,info])
call steqr(d, e [,z] [,compz] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues and (optionally) all the eigenvectors of a real symmetric tridiagonal matrix T . In other words, the routine can compute the spectral factorization: $T = Z^* \Lambda Z^T$. Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i ; Z is an orthogonal matrix whose columns are eigenvectors. Thus,

$$T^* z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

The routine normalizes the eigenvectors so that $\|z_i\|_2 = 1$.

You can also use the routine for computing the eigenvalues and eigenvectors of an arbitrary real symmetric (or complex Hermitian) matrix A reduced to tridiagonal form T : $A = Q^* T^* Q^H$.

In this case, the spectral factorization is as follows: $A = Q^* T^* Q^H = (Q^* Z)^* \Lambda (Q^* Z)^H$. Before calling `?steqr`, you must reduce A to tridiagonal form and generate the explicit matrix Q by calling the following routines:

	for real matrices:	for complex matrices:
full storage	?sytrd, ?orgtr	?hetrd, ?ungtr
packed storage	?sptrd, ?opgtr	?hptrd, ?upgtr
band storage	?sbtrd (<i>vect</i> ='V')	?hbtrd (<i>vect</i> ='V')

If you need eigenvalues only, it's more efficient to call `?sterf`. If T is positive-definite, `?pteqr` can compute small eigenvalues more accurately than `?steqr`.

To solve the problem by a single call, use one of the divide and conquer routines `?stevd`, `?syevd`, `?spevd`, or `?sbevd` for real symmetric matrices or `?heevd`, `?hpevd`, or `?hbevd` for complex Hermitian matrices.

Input Parameters

<i>compz</i>	CHARACTER*1. Must be 'N' or 'I' or 'V'. If <i>compz</i> = 'N', the routine computes eigenvalues only. If <i>compz</i> = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix T . If <i>compz</i> = 'V', the routine computes the eigenvalues and eigenvectors of A (and the array z must contain the matrix Q on entry).
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).

d, *e*, *work* REAL for single-precision flavors
 DOUBLE PRECISION for double-precision flavors.
 Arrays:
d(*) contains the diagonal elements of *T*.
 The dimension of *d* must be at least $\max(1, n)$.
e(*) contains the off-diagonal elements of *T*.
 The dimension of *e* must be at least $\max(1, n-1)$.
work(*) is a workspace array.
 The dimension of *work* must be:
 at least 1 if *compz* = 'N';
 at least $\max(1, 2*n-2)$ if *compz* = 'V' or 'I'.

z REAL for *ssteqr*
 DOUBLE PRECISION for *dsteqr*
 COMPLEX for *csteqr*
 DOUBLE COMPLEX for *zsteqr*.
 Array, DIMENSION (*ldz*, *)
 If *compz* = 'N' or 'I', *z* need not be set.
 If *vect* = 'V', *z* must contain the *n*-by-*n* matrix *Q*.
 The second dimension of *z* must be:
 at least 1 if *compz* = 'N';
 at least $\max(1, n)$ if *compz* = 'V' or 'I'.
work (*lwork*) is a workspace array.

ldz INTEGER. The first dimension of *z*. Constraints:
 $ldz \geq 1$ if *compz* = 'N';
 $ldz \geq \max(1, n)$ if *compz* = 'V' or 'I'.

Output Parameters

d The *n* eigenvalues in ascending order, unless *info* > 0.
 See also *info*.
e On exit, the array is overwritten; see *info*.
z If *info* = 0, contains the *n* orthonormal eigenvectors,
 stored by columns. (The *i*-th column corresponds to the
*i*th eigenvalue.)
info INTEGER.
 If *info* = 0, the execution is successful.

If $info = i$, the algorithm failed to find all the eigenvalues after $30n$ iterations: i off-diagonal elements have not converged to zero. On exit, d and e contain, respectively, the diagonal and off-diagonal elements of a tridiagonal matrix orthogonally similar to T .
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `steqr` interface are the following:

d	Holds the vector of length n .
e	Holds the vector of length $(n-1)$.
z	Holds the matrix Z of size (n, n) .
$compz$	<p>If omitted, this argument is restored based on the presence of argument z as follows: $compz = 'I'$, if z is present, $compz = 'N'$, if z is omitted. If present, $compz$ must be equal to 'I' or 'V' and the argument z must also be present. Note that there will be an error condition if $compz$ is present and z omitted. Note that two variants of Fortran 95 interface for <code>steqr</code> routine are needed because of an ambiguous choice between real and complex cases appear when z is omitted. Thus, the name <code>rsteqr</code> is used in real cases (single or double precision), and the name <code>steqr</code> is used in complex cases (single or double precision).</p>

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If λ_i is an exact eigenvalue, and μ_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \epsilon * \|T\|_2$$

where $c(n)$ is a modestly increasing function of n .

If z_i is the corresponding exact eigenvector, and w_i is the corresponding computed vector, then the angle $\theta(z_i, w_i)$ between them is bounded as follows:

$$\theta(z_i, w_i) \leq c(n) * \epsilon * \|T\|_2 / \min_{i \neq j} |\lambda_i - \lambda_j|.$$

The total number of floating-point operations depends on how rapidly the algorithm converges. Typically, it is about

$$24n^2 \text{ if } compz = 'N';$$

$$7n^3 \text{ (for complex flavors, } 14n^3) \text{ if } compz = 'V' \text{ or } 'I'.$$

stemr

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sstemr(jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz,
tryrac, work, lwork, iwork, liwork, info)
```

```
call dstemr(jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz,
tryrac, work, lwork, iwork, liwork, info)
```

```
call cstemr(jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz,
tryrac, work, lwork, iwork, liwork, info)
```

```
call zstemr(jobz, range, n, d, e, vl, vu, il, iu, m, w, z, ldz, nzc, isuppz,
tryrac, work, lwork, iwork, liwork, info)
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval $[vl, vu]$ or a range of indices $il:iu$ for the desired eigenvalues.

Depending on the number of desired eigenvalues, these are computed either by bisection or the *dqds* algorithm. Numerically orthogonal eigenvectors are computed by the use of various suitable L^*D*L^T factorizations near clusters of close eigenvalues (referred to as RRRs, Relatively Robust Representations). An informal sketch of the algorithm follows.

For each unreduced block (submatrix) of T ,

- a.** Compute $T - \text{sigma} * I = L * D * L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of L and D cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- b.** Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see steps c and d.
- c.** For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- d.** For each eigenvalue with a large enough relative separation compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to step c for any clusters that remain.

For more details, see: [Dhillon04], [Dhillon04-02], [Dhillon97]

The routine works only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs (NaN stands for "not a number"). This permits the use of efficient inner loops avoiding a check for zero divisors.

LAPACK routines can be used to reduce a complex Hermitean matrix to real symmetric tridiagonal form.

(Any complex Hermitean tridiagonal matrix has real values on its diagonal and potentially complex numbers on its off-diagonals. By applying a similarity transform with an appropriate diagonal matrix $\text{diag}(1, e^{i \text{phy}_1}, \dots, e^{i \text{phy}_{n-1}})$, the complex Hermitean matrix can be transformed into a real symmetric matrix and complex arithmetic can be entirely avoided.) While the eigenvectors of the real symmetric tridiagonal matrix are real, the eigenvectors of original complex Hermitean matrix have complex entries in general. Since LAPACK drivers overwrite the matrix data with the eigenvectors, *zstemr* accepts complex workspace to facilitate interoperability with *zunmtr* or *zupmtr*.

Input Parameters

jobz CHARACTER*1. Must be 'N' or 'V'.
If *jobz* = 'N', then only eigenvalues are computed.

	If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes all eigenvalues in the half-open interval: (<i>v1</i> , <i>vu</i>]. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>n</i>	INTEGER. The order of the matrix <i>T</i> ($n \geq 0$).
<i>d</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i>). Contains <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i> .
<i>e</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (<i>n</i> -1). Contains (<i>n</i> -1) off-diagonal elements of the tridiagonal matrix <i>T</i> in elements 1 to <i>n</i> -1 of <i>e</i> . <i>e</i> (<i>n</i>) need not be set on input, but is used internally as workspace.
<i>v1, vu</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. Constraint: $v1 < vu$. If <i>range</i> = 'A' or 'I', <i>v1</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	INTEGER. If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$. If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>ldz</i>	INTEGER. The leading dimension of the output array <i>z</i> . if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$; $ldz \geq 1$ otherwise.
<i>nzc</i>	INTEGER. The number of eigenvectors to be held in the array <i>z</i> . If <i>range</i> = 'A', then $nzc \geq \max(1, n)$;

If *range* = 'V', then *nzc* is greater than or equal to the number of eigenvalues in the half-open interval: (*vl*, *vu*].

If *range* = 'I', then $nzc \geq il + iu + 1$.

This value is returned as the first entry of the array *z*, and no error message related to *nzc* is issued by the routine *xerbla*.

tryrac

LOGICAL.

If *tryrac* = .TRUE., it indicates that the code should check whether the tridiagonal matrix defines its eigenvalues to high relative accuracy. If so, the code uses relative-accuracy preserving algorithms that might be (a bit) slower depending on the matrix. If the matrix does not define its eigenvalues to high relative accuracy, the code can use possibly faster algorithms.

If *tryrac* = .FALSE., the code is not required to guarantee relatively accurate eigenvalues and can use the fastest possible techniques.

work

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Workspace array, DIMENSION (*lwork*).

lwork

INTEGER.

The dimension of the array *work*,

$lwork \geq \max(1, 18 * n)$.

If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by *xerbla*.

iwork

INTEGER.

Workspace array, DIMENSION (*liwork*).

liwork

INTEGER.

The dimension of the array *iwork*.

$lwork \geq \max(1, 10 * n)$ if the eigenvectors are desired, and

$lwork \geq \max(1, 8 * n)$ if only the eigenvalues are to be computed.

If $liwork=-1$, then a workspace query is assumed; the routine only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued by $xerbla$.

Output Parameters

e	On exit, the array e is overwritten.
m	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If $range = 'A'$, then $m=n$, and if $range = 'I'$, then $m=i_u-i_l+1$.
w	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION (n). The first m elements contain the selected eigenvalues in ascending order.
z	REAL for $sstemr$ DOUBLE PRECISION for $dstemr$ COMPLEX for $cstemr$ DOUBLE COMPLEX for $zstemr$. Array $z(ldz, *)$, the second dimension of z must be at least $\max(1, m)$. If $jobz = 'V'$, and $info = 0$, then the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$. If $jobz = 'N'$, then z is not referenced. Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and can be computed with a workspace query by setting $nzc=-1$, see description of the parameter nzc .
$isuppz$	INTEGER. Array, DIMENSION ($2 * \max(1, m)$). The support of the eigenvectors in z , that is the indices indicating the nonzero elements in z . The i -th computed eigenvector is nonzero only in elements $isuppz(2*i-1)$

	through <code>isuppz(2*i)</code> . This is relevant in the case when the matrix is split. <code>isuppz</code> is only accessed when <code>jobz = 'V'</code> and <code>n>0</code> .
<code>tryrac</code>	On exit, <code>TRUE</code> . <code>tryrac</code> is set to <code>.FALSE</code> if the matrix does not define its eigenvalues to high relative accuracy.
<code>work(1)</code>	On exit, if <code>info = 0</code> , then <code>work(1)</code> returns the optimal (and minimal) size of <code>lwork</code> .
<code>iwork(1)</code>	On exit, if <code>info = 0</code> , then <code>iwork(1)</code> returns the optimal size of <code>liwork</code> .
<code>info</code>	INTEGER. If = 0, the execution is successful. If <code>info = -i</code> , the <code>i</code> -th parameter had an illegal value. If <code>info = 1</code> , internal error in <code>?larre</code> occurred, if <code>info = 2</code> , internal error in <code>?larrv</code> occurred.

?stedc

Computes all eigenvalues and eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method.

Syntax

FORTRAN 77:

```
call sstedc(compz, n, d, e, z, ldz, work, lwork, iwork, liwork, info)
call dstedc(compz, n, d, e, z, ldz, work, lwork, iwork, liwork, info)
call cstedc(compz, n, d, e, z, ldz, work, lwork, rwork, lrwork, iwork, liwork, info)
call zstedc(compz, n, d, e, z, ldz, work, lwork, rwork, lrwork, iwork, liwork, info)
```

Fortran 95:

```
call rstedc(d, e [,z] [,compz] [,info])
call stedc(d, e [,z] [,compz] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues and (optionally) all the eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric or complex Hermitian matrix can also be found if `?sytrd/?hetrd` or `?sptrd/?hptrd` or `?sbtrd/?hbtrd` has been used to reduce this matrix to tridiagonal form.

See also `?laed0`, `?laed1`, `?laed2`, `?laed3`, `?laed4`, `?laed5`, `?laed6`, `?laed7`, `?laed8`, `?laed9`, and `?laeda` used by this function.

Input Parameters

<i>compz</i>	CHARACTER*1. Must be 'N' or 'I' or 'V'. If <i>compz</i> = 'N', the routine computes eigenvalues only. If <i>compz</i> = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix. If <i>compz</i> = 'V', the routine computes the eigenvalues and eigenvectors of original symmetric/Hermitian matrix. On entry, the array <i>z</i> must contain the orthogonal/unitary matrix used to reduce the original matrix to tridiagonal form.
<i>n</i>	INTEGER. The order of the symmetric tridiagonal matrix ($n \geq 0$).
<i>d, e, rwork</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> (*) contains the diagonal elements of the tridiagonal matrix. The dimension of <i>d</i> must be at least $\max(1, n)$. <i>e</i> (*) contains the subdiagonal elements of the tridiagonal matrix. The dimension of <i>e</i> must be at least $\max(1, n-1)$. <i>rwork</i> is a workspace array, its dimension $\max(1, lrwork)$.
<i>z, work</i>	REAL for <code>sstedc</code> DOUBLE PRECISION for <code>dstedc</code> COMPLEX for <code>csstedc</code> DOUBLE COMPLEX for <code>zstedc</code> .

Arrays: $z(ldz, *)$, $work(*)$.

If $compz = 'V'$, then, on entry, z must contain the orthogonal/unitary matrix used to reduce the original matrix to tridiagonal form.

The second dimension of z must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

ldz

INTEGER. The first dimension of z . Constraints:

$ldz \geq 1$ if $compz = 'N'$;

$ldz \geq \max(1, n)$ if $compz = 'V'$ or $'I'$.

$lwork$

INTEGER. The dimension of the array $work$.

If $compz = 'N'$ or $'I'$, or $n \leq 1$, $lwork$ must be at least 1.

If $compz = 'V'$ and $n > 1$, $lwork$ must be at least $n*n$. Note that for $compz = 'V'$, and if n is less than or equal to the minimum divide size, usually 25, then $lwork$ need only be 1.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for the required value of $lwork$.

$lrwork$

INTEGER. The dimension of the array $rwork$ (used for complex flavors only).

If $compz = 'N'$, or $n \leq 1$, $lrwork$ must be at least 1.

If $compz = 'V'$ and $n > 1$, $lrwork$ must be at least $(1+3*n+2*n*\lg(n)+3*n*n)$, where $\lg(n)$ is the smallest integer k such that $2**k \geq n$.

If $compz = 'I'$ and $n > 1$, $lrwork$ must be at least $(1+4*n+2*n*n)$.

Note that for $compz = 'V'$ or $'I'$, and if n is less than or equal to the minimum divide size, usually 25, then $lrwork$ need only be $\max(1, 2*(n-1))$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for the required value of $lwork$.

$iwork$ INTEGER. Workspace array, its dimension $\max(1, liwork)$.
 $liwork$ INTEGER. The dimension of the array $iwork$.

If $compz = 'N'$, or $n \leq 1$, $liwork$ must be at least 1.

If $compz = 'V'$ and $n > 1$, $liwork$ must be at least $(6+6*n+5*n*\lg(n))$, where $\lg(n)$ is the smallest integer k such that $2**k \geq n$.

If $compz = 'I'$ and $n > 1$, $liwork$ must be at least $(3+5*n)$.

Note that for $compz = 'V'$ or $'I'$, and if n is less than or equal to the minimum divide size, usually 25, then $liwork$ need only be 1.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for the required value of $liwork$.

Output Parameters

d The n eigenvalues in ascending order, unless $info \neq 0$. See also $info$.

e On exit, the array is overwritten; see $info$.

z If $info = 0$, then if $compz = 'V'$, z contains the orthonormal eigenvectors of the original symmetric/Hermitian matrix, and if $compz = 'I'$, z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $compz = 'N'$, z is not referenced.

$work(1)$ On exit, if $info = 0$, then $work(1)$ returns the optimal $lwork$.

<i>rwork(1)</i>	On exit, if <i>info</i> = 0, then <i>rwork(1)</i> returns the optimal <i>lrwork</i> (for complex flavors only).
<i>iwork(1)</i>	On exit, if <i>info</i> = 0, then <i>iwork(1)</i> returns the optimal <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns <i>i</i> /(<i>n</i> +1) through mod(<i>i</i> , <i>n</i> +1).

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *stedc* interface are the following:

<i>d</i>	Holds the vector of length <i>n</i> .
<i>e</i>	Holds the vector of length (<i>n</i> -1).
<i>z</i>	Holds the matrix <i>z</i> of size (<i>n</i> , <i>n</i>).
<i>compz</i>	If omitted, this argument is restored based on the presence of argument <i>z</i> as follows: <i>compz</i> = 'I', if <i>z</i> is present, <i>compz</i> = 'N', if <i>z</i> is omitted. If present, <i>compz</i> must be equal to 'I' or 'V' and the argument <i>z</i> must also be present. Note that there will be an error condition if <i>compz</i> is present and <i>z</i> omitted.

Note that two variants of Fortran 95 interface for *stedc* routine are needed because of an ambiguous choice between real and complex cases appear when *z* and *work* are omitted. Thus, the name *rstedc* is used in real cases (single or double precision), and the name *stedc* is used in complex cases (single or double precision).

Application Notes

The required size of workspace arrays must be as follows.

For *sstedc*/*dstedc*:

If *compz* = 'N' or *n* ≤ 1 then *lwork* must be at least 1.

If *compz* = 'V' and $n > 1$ then *lwork* must be at least $(1 + 3n + 2n \cdot \lg n + 3n^2)$, where $\lg(n)$ = smallest integer k such that $2^k \geq n$.

If *compz* = 'I' and $n > 1$ then *lwork* must be at least $(1 + 4n + n^2)$.

If *compz* = 'N' or $n \leq 1$ then *liwork* must be at least 1.

If *compz* = 'V' and $n > 1$ then *liwork* must be at least $(6 + 6n + 5n \cdot \lg n)$.

If *compz* = 'I' and $n > 1$ then *liwork* must be at least $(3 + 5n)$.

For *cstedc/zstedc*:

If *compz* = 'N' or 'I', or $n \leq 1$, *lwork* must be at least 1.

If *compz* = 'V' and $n > 1$, *lwork* must be at least n^2 .

If *compz* = 'N' or $n \leq 1$, *lrwork* must be at least 1.

If *compz* = 'V' and $n > 1$, *lrwork* must be at least $(1 + 3n + 2n \cdot \lg n + 3n^2)$, where $\lg(n)$ = smallest integer k such that $2^k \geq n$.

If *compz* = 'I' and $n > 1$, *lrwork* must be at least $(1 + 4n + 2n^2)$.

The required value of *liwork* for complex flavors is the same as for real flavors.

If *lwork* (or *liwork* or *lrwork*, if supplied) is equal to -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*, *lrwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?stegr

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sstegr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz,
work, lwork, iwork, liwork, info)
```

```
call dstegr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz,
work, lwork, iwork, liwork, info)
```

```
call cstegr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz,
work, lwork, iwork, liwork, info)
```

```
call zstegr(jobz, range, n, d, e, vl, vu, il, iu, abstol, m, w, z, ldz, isuppz,
work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call rstegr(d, e, w [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol]
[,info])
```

```
call stegr(d, e, w [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol]
[,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . Any such unreduced matrix has a well defined set of pairwise different real eigenvalues, the corresponding real eigenvectors are pairwise orthogonal.

The spectrum may be computed either completely or partially by specifying either an interval $(vl, vu]$ or a range of indices $il:iu$ for the desired eigenvalues.

`?sregr` is a compatibility wrapper around the improved `?stemr` routine. See its description for further details.

Note that the `abstol` parameter no longer provides any benefit and hence is no longer used.

See also auxiliary `?lasq2` `?lasq5`, `?lasq6`, used by this routine.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval:

$vl < \lambda(i) \leq vu$.
 If *range* = 'I', the routine computes eigenvalues with indices *il* to *iu*.

n INTEGER. The order of the matrix *T* ($n \geq 0$).

d, e, work REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Arrays:
d(*) contains the diagonal elements of *T*.
 The dimension of *d* must be at least $\max(1, n)$.
e(*) contains the subdiagonal elements of *T* in elements 1 to *n*-1; *e*(*n*) need not be set on input, but it is used as a workspace.
 The dimension of *e* must be at least $\max(1, n)$.
work(*lwork*) is a workspace array.

vl, vu REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
 Constraint: $vl < vu$.
 If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu INTEGER.
 If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
 Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$.
 If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Unused. Was the absolute error tolerance for the eigenvalues/eigenvectors in previous versions.

ldz INTEGER. The leading dimension of the output array *z*.
 Constraints:
 $ldz < 1$ if *jobz* = 'N';
 $ldz < \max(1, n)$ if *jobz* = 'V', and

lwork INTEGER.
 The dimension of the array *work*,
 $lwork \geq \max(1, 18*n)$ if *jobz* = 'V', and

$lwork \geq \max(1, 12*n)$ if $jobz = 'N'$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#). See *Application Notes* below for details.

$iwork$

INTEGER.

Workspace array, DIMENSION ($liwork$).

$liwork$

INTEGER.

The dimension of the array $iwork$, $lwork \geq \max(1, 10*n)$

if the eigenvectors are desired, and $lwork \geq \max(1, 8*n)$

if only the eigenvalues are to be computed..

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued by [xerbla](#).

See *Application Notes* below for details.

Output Parameters

d, e

On exit, d and e are overwritten.

m

INTEGER. The total number of eigenvalues found,

$0 \leq m \leq n$.

If $range = 'A'$, $m = n$, and if $range = 'I'$, $m = iu-il+1$.

w

REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.

Array, DIMENSION at least $\max(1, n)$.

The selected eigenvalues in ascending order, stored in $w(1)$ to $w(m)$.

z

REAL for `sstegr`

DOUBLE PRECISION for `dstegr`

COMPLEX for `cstegr`

DOUBLE COMPLEX for `zstegr`.

Array $z(ldz, *)$, the second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, and if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$. If $jobz = 'N'$, then z is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used. Supplying n columns is always safe.

isuppz

INTEGER.

Array, DIMENSION at least $(2 * \max(1, m))$.

The support of the eigenvectors in z , that is the indices indicating the nonzero elements in z . The i -th computed eigenvector is nonzero only in elements $isuppz(2*i-1)$ through $isuppz(2*i)$. This is relevant in the case when the matrix is split. $isuppz$ is only accessed when $jobz = 'V'$, and $n > 0$.

work(1)

On exit, if $info = 0$, then *work(1)* returns the required minimal size of *lwork*.

iwork(1)

On exit, if $info = 0$, then *iwork(1)* returns the required minimal size of *liwork*.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = 1x$, internal error in ?larre occurred,

If $info = 2x$, internal error in ?larrv occurred. Here the digit $x = \text{abs}(iinfo) < 10$, where $iinfo$ is the non-zero error code returned by ?larre or ?larrv, respectively.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stegr` interface are the following:

d Holds the vector of length n .

e Holds the vector of length n .

<i>w</i>	Holds the vector of length <i>n</i> .
<i>z</i>	Holds the matrix <i>z</i> of size (<i>n,m</i>).
<i>isuppz</i>	Holds the vector of length (<i>2*m</i>).
<i>v1</i>	Default value for this argument is $v1 = - \text{HUGE} (v1)$ where $\text{HUGE}(a)$ means the largest machine number of the same precision as argument <i>a</i> .
<i>vu</i>	Default value for this argument is $vu = \text{HUGE} (v1)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this argument is $abstol = 0.0_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>v1</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>v1</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>v1</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>v1</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Note that two variants of Fortran 95 interface for *stegr* routine are needed because of an ambiguous choice between real and complex cases appear when *z* is omitted. Thus, the name *rstegr* is used in real cases (single or double precision), and the name *stegr* is used in complex cases (single or double precision).

Application Notes

Currently *?stegr* is only set up to find *all* the *n* eigenvalues and eigenvectors of *T* in $O(n^2)$ time, that is, only $range = 'A'$ is supported.

?stegr works only on machines which follow IEEE-754 floating-point standard in their handling of infinities and NaNs. Normal execution of *?stegr* may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the IEEE-754 standard.

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run, or set $lwork = -1$ ($liwork = -1$).

If $lwork$ (or $liwork$) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$) on exit. Use this value ($work(1)$, $iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$). This operation is called a workspace query.

Note that if $lwork$ ($liwork$) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?pteqr

Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric positive-definite tridiagonal matrix.

Syntax

FORTRAN 77:

```
call spteqr(compz, n, d, e, z, ldz, work, info)
call dpteqr(compz, n, d, e, z, ldz, work, info)
call cpteqr(compz, n, d, e, z, ldz, work, info)
call zpteqr(compz, n, d, e, z, ldz, work, info)
```

Fortran 95:

```
call rpteqr(d, e [,z] [,compz] [,info])
call pteqr(d, e [,z] [,compz] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues and (optionally) all the eigenvectors of a real symmetric positive-definite tridiagonal matrix T . In other words, the routine can compute the spectral factorization: $T = Z\Lambda Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i ; Z is an orthogonal matrix whose columns are eigenvectors. Thus,

$$T^*z_i = \lambda_i * z_i \text{ for } i = 1, 2, \dots, n.$$

(The routine normalizes the eigenvectors so that $\|z_i\|_2 = 1$.)

You can also use the routine for computing the eigenvalues and eigenvectors of real symmetric (or complex Hermitian) positive-definite matrices A reduced to tridiagonal form $T: A = Q^*T^*Q^H$.

In this case, the spectral factorization is as follows: $A = Q^*T^*Q^H = (QZ)^*\Lambda^*(QZ)^H$. Before calling `?pteqr`, you must reduce A to tridiagonal form and generate the explicit matrix Q by calling the following routines:

	for real matrices:	for complex matrices:
full storage	?sytrd, ?orgtr	?hetrd, ?ungtr
packed storage	?sptrd, ?opgtr	?hptrd, ?upgtr
band storage	?sbtrd (<i>vect</i> ='V')	?hbtrd (<i>vect</i> ='V')

The routine first factorizes T as $L^*D^*L^H$ where L is a unit lower bidiagonal matrix, and D is a diagonal matrix. Then it forms the bidiagonal matrix $B = L^*D^{1/2}$ and calls `?bdsqr` to compute the singular values of B , which are the same as the eigenvalues of T .

Input Parameters

<i>compz</i>	CHARACTER*1. Must be 'N' or 'I' or 'V'. If <i>compz</i> = 'N', the routine computes eigenvalues only. If <i>compz</i> = 'I', the routine computes the eigenvalues and eigenvectors of the tridiagonal matrix T . If <i>compz</i> = 'V', the routine computes the eigenvalues and eigenvectors of A (and the array z must contain the matrix Q on entry).
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>d, e, work</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Arrays: <i>d</i> (*) contains the diagonal elements of T .

The dimension of d must be at least $\max(1, n)$.
 $e(*)$ contains the off-diagonal elements of T .
The dimension of e must be at least $\max(1, n-1)$.
 $work(*)$ is a workspace array.
The dimension of $work$ must be:
at least 1 if $compz = 'N'$;
at least $\max(1, 4*n-4)$ if $compz = 'V'$ or $'I'$.

z REAL for `spteqr`
DOUBLE PRECISION for `dppteqr`
COMPLEX for `cppteqr`
DOUBLE COMPLEX for `zpptrqr`.
Array, DIMENSION ($ldz, *$)
If $compz = 'N'$ or $'I'$, z need not be set.
If $vect = 'V'$, z must contain the n -by- n matrix Q .
The second dimension of z must be:
at least 1 if $compz = 'N'$;
at least $\max(1, n)$ if $compz = 'V'$ or $'I'$.

ldz INTEGER. The first dimension of z . Constraints:
 $ldz \geq 1$ if $compz = 'N'$;
 $ldz \geq \max(1, n)$ if $compz = 'V'$ or $'I'$.

Output Parameters

d The n eigenvalues in descending order, unless $info > 0$.
See also $info$.

e On exit, the array is overwritten.

z If $info = 0$, contains the n orthonormal eigenvectors,
stored by columns. (The i -th column corresponds to the
 i -th eigenvalue.)

$info$ INTEGER.
If $info = 0$, the execution is successful.
If $info = i$, the leading minor of order i (and hence T
itself) is not positive-definite.
If $info = n + i$, the algorithm for computing singular
values failed to converge; i off-diagonal elements have not
converged to zero.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `p_teqr` interface are the following:

<code>d</code>	Holds the vector of length n .
<code>e</code>	Holds the vector of length $(n-1)$.
<code>z</code>	Holds the matrix z of size (n, n) .
<code>compz</code>	<p>If omitted, this argument is restored based on the presence of argument z as follows:</p> <p><code>compz</code> = 'I', if z is present, <code>compz</code> = 'N', if z is omitted.</p> <p>If present, <code>compz</code> must be equal to 'I' or 'V' and the argument z must also be present. Note that there will be an error condition if <code>compz</code> is present and z omitted.</p>

Note that two variants of Fortran 95 interface for `p_teqr` routine are needed because of an ambiguous choice between real and complex cases appear when z is omitted. Thus, the name `rpteqr` is used in real cases (single or double precision), and the name `p_teqr` is used in complex cases (single or double precision).

Application Notes

If λ_i is an exact eigenvalue, and μ_i is the corresponding computed value, then

$$|\mu_i - \lambda_i| \leq c(n) * \epsilon * K * \lambda_i$$

where $c(n)$ is a modestly increasing function of n , ϵ is the machine precision, and $K = \| |DTD| \|_2 * \| (DTD)^{-1} \|_2$, D is diagonal with $d_{ii} = t_{ii}^{-1/2}$.

If z_i is the corresponding exact eigenvector, and w_i is the corresponding computed vector, then the angle $\theta(z_i, w_i)$ between them is bounded as follows:

$$\theta(u_i, w_i) \leq c(n)\epsilon K / \min_{i \neq j} (|\lambda_i - \lambda_j| / |\lambda_i + \lambda_j|).$$

Here $\min_{i \neq j} (|\lambda_i - \lambda_j| / |\lambda_i + \lambda_j|)$ is the *relative gap* between λ_i and the other eigenvalues.

The total number of floating-point operations depends on how rapidly the algorithm converges.

Typically, it is about

$30n^2$ if *compz* = 'N';
 $6n^3$ (for complex flavors, $12n^3$) if *compz* = 'V' or 'I'.

?stebz

Computes selected eigenvalues of a real symmetric tridiagonal matrix by bisection.

Syntax

FORTRAN 77:

```
call sstebz (range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit, w,
            iblock, isplit, work, iwork, info)
call dstebz (range, order, n, vl, vu, il, iu, abstol, d, e, m, nsplit, w,
            iblock, isplit, work, iwork, info)
```

Fortran 95:

```
call stebz(d, e, m, nsplit, w, iblock, isplit [, order] [,vl] [,vu] [,il]
           [,iu] [,abstol] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes some (or all) of the eigenvalues of a real symmetric tridiagonal matrix T by bisection. The routine searches for zero or negligible off-diagonal elements to see if T splits into block-diagonal form $T = \text{diag}(T_1, T_2, \dots)$. Then it performs bisection on each of the blocks T_i and returns the block index of each computed eigenvalue, so that a subsequent call to [?stein](#) can also take advantage of the block structure.

See also [?laebz](#).

Input Parameters

range CHARACTER*1. Must be 'A' or 'V' or 'I'.
 If *range* = 'A', the routine computes all eigenvalues.
 If *range* = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$.

If *range* = 'I', the routine computes eigenvalues with indices *il* to *iu*.

order CHARACTER*1. Must be 'B' or 'E'.
 If *order* = 'B', the eigenvalues are to be ordered from smallest to largest within each split-off block.
 If *order* = 'E', the eigenvalues for the entire matrix are to be ordered from smallest to largest.

n INTEGER. The order of the matrix T ($n \geq 0$).

vl, vu REAL for *sstebz*
 DOUBLE PRECISION for *dstebz*.
 If *range* = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval:
 $vl < \lambda(i) \leq vu$.
 If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu INTEGER. Constraint: $1 \leq il \leq iu \leq n$.
 If *range* = 'I', the routine computes eigenvalues $\lambda(i)$ such that $il \leq i \leq iu$ (assuming that the eigenvalues $\lambda(i)$ are in ascending order).
 If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol REAL for *sstebz*
 DOUBLE PRECISION for *dstebz*.
 The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width *abstol*.
 If $abstol \leq 0.0$, then the tolerance is taken as $\text{eps} * |T|$, where *eps* is the machine precision, and $|T|$ is the 1-norm of the matrix T .

d, e, work REAL for *sstebz*
 DOUBLE PRECISION for *dstebz*.
 Arrays:
d(*) contains the diagonal elements of T .
 The dimension of *d* must be at least $\max(1, n)$.
e(*) contains the off-diagonal elements of T .
 The dimension of *e* must be at least $\max(1, n-1)$.
work(*) is a workspace array.

iwork The dimension of *work* must be at least $\max(1, 4n)$.
 INTEGER. Workspace.
 Array, DIMENSION at least $\max(1, 3n)$.

Output Parameters

m INTEGER. The actual number of eigenvalues found.

nsplit INTEGER. The number of diagonal blocks detected in *T*.

w REAL for *sstebz*
 DOUBLE PRECISION for *dstebz*.
 Array, DIMENSION at least $\max(1, n)$. The computed eigenvalues, stored in *w*(1) to *w*(*m*).

iblock, isplit INTEGER.
 Arrays, DIMENSION at least $\max(1, n)$.
 A positive value *iblock*(*i*) is the block number of the eigenvalue stored in *w*(*i*) (see also *info*).
 The leading *nsplit* elements of *isplit* contain points at which *T* splits into blocks *T_i* as follows: the block *T₁* contains rows/columns 1 to *isplit*(1); the block *T₂* contains rows/columns *isplit*(1)+1 to *isplit*(2), and so on.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = 1, for *range* = 'A' or 'V', the algorithm failed to compute some of the required eigenvalues to the desired accuracy; *iblock*(*i*) < 0 indicates that the eigenvalue stored in *w*(*i*) failed to converge.
 If *info* = 2, for *range* = 'I', the algorithm failed to compute some of the required eigenvalues. Try calling the routine again with *range* = 'A'.
 If *info* = 3:
 for *range* = 'A' or 'V', same as *info* = 1;
 for *range* = 'I', same as *info* = 2.
 If *info* = 4, no eigenvalues have been computed. The floating-point arithmetic on the computer is not behaving as expected.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stebz` interface are the following:

<code>d</code>	Holds the vector of length n .
<code>e</code>	Holds the vector of length $(n-1)$.
<code>w</code>	Holds the vector of length n .
<code>iblock</code>	Holds the vector of length n .
<code>isplit</code>	Holds the vector of length n .
<code>order</code>	Must be 'B' or 'E'. The default value is 'B'.
<code>v1</code>	Default value for this argument is $v1 = -HUGE(v1)$ where $HUGE(a)$ means the largest machine number of the same precision as argument a .
<code>vu</code>	Default value for this argument is $vu = HUGE(v1)$.
<code>il</code>	Default value for this argument is $il = 1$.
<code>iu</code>	Default value for this argument is $iu = n$.
<code>abstol</code>	Default value for this argument is $abstol = 0.0_WP$.
<code>range</code>	Restored based on the presence of arguments $v1, vu, il, iu$ as follows: $range = 'V'$, if one of or both $v1$ and vu are present, $range = 'I'$, if one of or both il and iu are present, $range = 'A'$, if none of $v1, vu, il,$ iu is present, Note that there will be an error condition if one of or both $v1$ and vu are present and at the same time one of or both il and iu are present.

Application Notes

The eigenvalues of T are computed to high relative accuracy which means that if they vary widely in magnitude, then any small eigenvalues will be computed more accurately than, for example, with the standard QR method. However, the reduction to tridiagonal form (prior to calling the routine) may exclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix if its eigenvalues vary widely in magnitude.

?stein

Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix.

Syntax

FORTRAN 77:

```
call sstein(n, d, e, m, w, iblock, isplit, z, ldz, work, iwork, ifailv, info)
call dstein(n, d, e, m, w, iblock, isplit, z, ldz, work, iwork, ifailv, info)
call cstein(n, d, e, m, w, iblock, isplit, z, ldz, work, iwork, ifailv, info)
call zstein(n, d, e, m, w, iblock, isplit, z, ldz, work, iwork, ifailv, info)
```

Fortran 95:

```
call stein(d, e, w, iblock, isplit, z [,ifailv] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, by inverse iteration. It is designed to be used in particular after the specified eigenvalues have been computed by `?stebz` with `order = 'B'`, but may also be used when the eigenvalues have been computed by other routines.

If you use this routine after `?stebz`, it can take advantage of the block structure by performing inverse iteration on each block T_i separately, which is more efficient than using the whole matrix T .

If T has been formed by reduction of a full symmetric or Hermitian matrix A to tridiagonal form, you can transform eigenvectors of T to eigenvectors of A by calling `?ormtr` or `?opmtr` (for real flavors) or by calling `?unmtr` or `?upmtr` (for complex flavors).

Input Parameters

n	INTEGER. The order of the matrix T ($n \geq 0$).
m	INTEGER. The number of eigenvectors to be returned.
d, e, w	REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Arrays:

$d(*)$ contains the diagonal elements of T .

The dimension of d must be at least $\max(1, n)$.

$e(*)$ contains the sub-diagonal elements of T stored in elements 1 to $n-1$

The dimension of e must be at least $\max(1, n-1)$.

$w(*)$ contains the eigenvalues of T , stored in $w(1)$ to $w(m)$ (as returned by `?stebz`). Eigenvalues of T_1 must be supplied first, in non-decreasing order; then those of T_2 , again in non-decreasing order, and so on. Constraint:

if $iblock(i) = iblock(i+1), w(i) \leq w(i+1)$.

The dimension of w must be at least $\max(1, n)$.

iblock, isplit

INTEGER.

Arrays, DIMENSION at least $\max(1, n)$. The arrays *iblock* and *isplit*, as returned by `?stebz` with *order* = 'B'.

If you did not call `?stebz` with *order* = 'B', set all elements of *iblock* to 1, and *isplit*(1) to n .)

ldz

INTEGER. The first dimension of the output array *z*; $ldz \geq \max(1, n)$.

work

REAL for single-precision flavors

DOUBLE PRECISION for double-precision flavors.

Workspace array, DIMENSION at least $\max(1, 5n)$.

iwork

INTEGER.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

z

REAL for *sstein*

DOUBLE PRECISION for *dstein*

COMPLEX for *cstein*

DOUBLE COMPLEX for *zstein*.

Array, DIMENSION (*ldz*, *).

If *info* = 0, *z* contains the *m* orthonormal eigenvectors, stored by columns. (The *i*th column corresponds to the *i*-th specified eigenvalue.)

ifailv

INTEGER.

Array, DIMENSION at least $\max(1, m)$.
 If $info = i > 0$, the first i elements of $ifailv$ contain the indices of any eigenvectors that failed to converge.

info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = i$, then i eigenvectors (as indicated by the parameter $ifailv$) each failed to converge in 5 iterations. The current iterates are stored in the corresponding columns of the array z .
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `stein` interface are the following:

<i>d</i>	Holds the vector of length n .
<i>e</i>	Holds the vector of length n .
<i>w</i>	Holds the vector of length n .
<i>iblock</i>	Holds the vector of length n .
<i>isplit</i>	Holds the vector of length n .
<i>z</i>	Holds the matrix Z of size (n, m) .
<i>ifailv</i>	Holds the vector of length (m) .

Application Notes

Each computed eigenvector z_i is an exact eigenvector of a matrix $T+E_i$, where $\|E_i\|_2 = O(\epsilon) * \|T\|_2$. However, a set of eigenvectors computed by this routine may not be orthogonal to so high a degree of accuracy as those computed by `?steqr`.

?disna

Computes the reciprocal condition numbers for the eigenvectors of a symmetric/ Hermitian matrix or for the left or right singular vectors of a general matrix.

Syntax

FORTRAN 77:

```
call sdisna(job, m, n, d, sep, info)
```

```
call ddisna(job, m, n, d, sep, info)
```

Fortran 95:

```
call disna(d, sep [,job] [,minmn] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m -by- n matrix.

The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the i -th computed vector is given by

```
slamch('E')*(anorm/sep(i))
```

where $anorm = ||A||_2 = \max(|d(j)|)$. $sep(i)$ is not allowed to be smaller than `slamch('E')*anorm` in order to limit the size of the error bound.

?disna may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

Input Parameters

<i>job</i>	CHARACTER*1. Must be 'E', 'L', or 'R'. Specifies for which problem the reciprocal condition numbers should be computed:
------------	---

$job = 'E'$: for the eigenvectors of a symmetric/Hermitian matrix;
 $job = 'L'$: for the left singular vectors of a general matrix;
 $job = 'R'$: for the right singular vectors of a general matrix.

m INTEGER. The number of rows of the matrix ($m \geq 0$).

n INTEGER.
 If $job = 'L'$, or $'R'$, the number of columns of the matrix ($n \geq 0$). Ignored if $job = 'E'$.

d REAL for `sdisna`
 DOUBLE PRECISION for `ddisna`.
 Array, dimension at least $\max(1,m)$ if $job = 'E'$, and at least $\max(1, \min(m,n))$ if $job = 'L'$ or $'R'$.
 This array must contain the eigenvalues (if $job = 'E'$) or singular values (if $job = 'L'$ or $'R'$) of the matrix, in either increasing or decreasing order.
 If singular values, they must be non-negative.

Output Parameters

sep REAL for `sdisna`
 DOUBLE PRECISION for `ddisna`.
 Array, dimension at least $\max(1,m)$ if $job = 'E'$, and at least $\max(1, \min(m,n))$ if $job = 'L'$ or $'R'$. The reciprocal condition numbers of the vectors.

info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `disna` interface are the following:

d Holds the vector of length $\min(m,n)$.
sep Holds the vector of length $\min(m,n)$.
job Must be $'E'$, $'L'$, or $'R'$. The default value is $'E'$.

minmn Indicates which of the values *m* or *n* is smaller. Must be either 'M' or 'N', the default is 'M'.
 If *job* = 'E', this argument is superfluous, If *job* = 'L' or 'R', this argument is used by the routine.

Generalized Symmetric-Definite Eigenvalue Problems

Generalized symmetric-definite eigenvalue problems are as follows: find the eigenvalues λ and the corresponding eigenvectors z that satisfy one of these equations:

$$Az = \lambda Bz, ABz = \lambda z, \text{ or } BAz = \lambda z,$$

where A is an n -by- n symmetric or Hermitian matrix, and B is an n -by- n symmetric positive-definite or Hermitian positive-definite matrix.

In these problems, there exist n real eigenvectors corresponding to real eigenvalues (even for complex Hermitian matrices A and B).

Routines described in this section allow you to reduce the above generalized problems to standard symmetric eigenvalue problem $Cy = \lambda y$, which you can solve by calling LAPACK routines described earlier in this chapter (see [Symmetric Eigenvalue Problems](#)).

Different routines allow the matrices to be stored either conventionally or in packed storage. Prior to reduction, the positive-definite matrix B must first be factorized using either `?potrf` or `?pptrf`.

The reduction routine for the banded matrices A and B uses a split Cholesky factorization for which a specific routine `?pbstf` is provided. This refinement halves the amount of work required to form matrix C .

[Table 4-4](#) lists LAPACK routines (FORTRAN 77 interface) that can be used to solve generalized symmetric-definite eigenvalue problems. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-4 Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

Matrix type	Reduce to standard problems (full storage)	Reduce to standard problems (packed storage)	Reduce to standard problems (band matrices)	Factorize band matrix
real symmetric matrices	<code>?sygst</code>	<code>?spgst</code>	<code>?sbgst</code>	<code>?pbstf</code>

Matrix type	Reduce to standard problems (full storage)	Reduce to standard problems (packed storage)	Reduce to standard problems (band matrices)	Factorize band matrix
complex Hermitian matrices	?hegst	?hpgst	?hbgst	?pbstf

?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

Syntax

FORTRAN 77:

```
call ssgst(itype, uplo, n, a, lda, b, ldb, info)
call dsgst(itype, uplo, n, a, lda, b, ldb, info)
```

Fortran 95:

```
call sygst(a, b [,itype] [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reduces real symmetric-definite generalized eigenproblems

$$A*z = \lambda*B*z, \quad A*B*z = \lambda*z, \quad \text{or} \quad B*A*z = \lambda*z$$

to the standard form $C*y = \lambda*y$. Here A is a real symmetric matrix, and B is a real symmetric positive-definite matrix. Before calling this routine, call ?potrf to compute the Cholesky factorization: $B = U^T*U$ or $B = L*L^T$.

Input Parameters

itype INTEGER. Must be 1 or 2 or 3.
 If *itype* = 1, the generalized eigenproblem is $A*z = \lambda*B*z$
 for *uplo* = 'U': $C = \text{inv}(U^T)*A*\text{inv}(U)$, $z = \text{inv}(U)*y$;

```

for uplo = 'L':  $C = \text{inv}(L) * A * \text{inv}(L^T)$ ,  $z = \text{inv}(L^T) * y$ .
If itype = 2, the generalized eigenproblem is  $A * B * z = \lambda * z$ 
for uplo = 'U':  $C = U * A * U^T$ ,  $z = \text{inv}(U) * y$ ;
for uplo = 'L':  $C = L^T * A * L$ ,  $z = \text{inv}(L^T) * y$ .
If itype = 3, the generalized eigenproblem is  $B * A * z = \lambda * z$ 
for uplo = 'U':  $C = U * A * U^T$ ,  $z = U^T * y$ ;
for uplo = 'L':  $C = L^T * A * L$ ,  $z = L * y$ .

uplo CHARACTER*1. Must be 'U' or 'L'.
If uplo = 'U', the array a stores the upper triangle of A;
you must supply B in the factored form  $B = U^T * U$ .
If uplo = 'L', the array a stores the lower triangle of A;
you must supply B in the factored form  $B = L * L^T$ .

n INTEGER. The order of the matrices A and B ( $n \geq 0$ ).

a, b REAL for ssygst
DOUBLE PRECISION for dsygst.
Arrays:
a(lda,*) contains the upper or lower triangle of A.
The second dimension of a must be at least  $\max(1, n)$ .
b(l db,*) contains the Cholesky-factored matrix B:
 $B = U^T * U$  or  $B = L * L^T$  (as returned by ?potrf).
The second dimension of b must be at least  $\max(1, n)$ .

lda INTEGER. The first dimension of a; at least  $\max(1, n)$ .
ldb INTEGER. The first dimension of b; at least  $\max(1, n)$ .

```

Output Parameters

```

a The upper or lower triangle of A is overwritten by the upper
or lower triangle of C, as specified by the arguments itype
and uplo.

info INTEGER.
If info = 0, the execution is successful.
If info = -i, the i-th parameter had an illegal value.

```

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `sygst` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size (n, n) .
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

Forming the reduced matrix C is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if `itype` = 1) or B (if `itype` = 2 or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?hegst

Reduces a complex Hermitian-definite generalized eigenvalue problem to the standard form.

Syntax

FORTRAN 77:

```
call chegst(itype, uplo, n, a, lda, b, ldb, info)
```

```
call zhegst(itype, uplo, n, a, lda, b, ldb, info)
```

Fortran 95:

```
call hegst(a, b [,itype] [,uplo] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine reduces complex Hermitian-definite generalized eigenvalue problems

$A*x = \lambda*B*x$, $A*B*x = \lambda*x$, or $B*A*x = \lambda*x$.

to the standard form $Cy = \lambda y$. Here the matrix A is complex Hermitian, and B is complex Hermitian positive-definite. Before calling this routine, you must call `?potrf` to compute the Cholesky factorization: $B = U^H*U$ or $B = L*L^H$.

Input Parameters

itype INTEGER. Must be 1 or 2 or 3.
 If *itype* = 1, the generalized eigenproblem is $A*z = \lambda*B*z$
 for *uplo* = 'U': $C = \text{inv}(U^H)*A*\text{inv}(U)$, $z = \text{inv}(U)*y$;
 for *uplo* = 'L': $C = \text{inv}(L)*A*\text{inv}(L^H)$, $z = \text{inv}(L^H)*y$.
 If *itype* = 2, the generalized eigenproblem is $A*B*z = \lambda*z$
 for *uplo* = 'U': $C = U*A*U^H$, $z = \text{inv}(U)*y$;
 for *uplo* = 'L': $C = L^H*A*L$, $z = \text{inv}(L^H)*y$.
 If *itype* = 3, the generalized eigenproblem is $B*A*z = \lambda*z$
 for *uplo* = 'U': $C = U*A*U^H$, $z = U^H*y$;
 for *uplo* = 'L': $C = L^H*A*L$, $z = L*y$.

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', the array *a* stores the upper triangle of A ;
 you must supply B in the factored form $B = U^H*U$.
 If *uplo* = 'L', the array *a* stores the lower triangle of A ;
 you must supply B in the factored form $B = L*L^H$.

n INTEGER. The order of the matrices A and B ($n \geq 0$).

a, *b* COMPLEX for chegstDOUBLE COMPLEX for zhegst.
 Arrays:
a(*lda*,*) contains the upper or lower triangle of A .
 The second dimension of *a* must be at least $\max(1, n)$.
b(*ldb*,*) contains the Cholesky-factored matrix B :
 $B = U^H*U$ or $B = L*L^H$ (as returned by `?potrf`).
 The second dimension of *b* must be at least $\max(1, n)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

ldb INTEGER. The first dimension of *b*; at least $\max(1, n)$.

Output Parameters

<i>a</i>	The upper or lower triangle of <i>A</i> is overwritten by the upper or lower triangle of <i>C</i> , as specified by the arguments <i>itype</i> and <i>uplo</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hegst` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (n, n) .
<i>itype</i>	Must be 1, 2, or 3. The default value is 1.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

Forming the reduced matrix *C* is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if *itype* = 1) or *B* (if *itype* = 2 or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if *B* is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?spgst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form using packed storage.

Syntax

FORTRAN 77:

```
call sspgst(itype, uplo, n, ap, bp, info)
```

```
call dspgst(itype, uplo, n, ap, bp, info)
```

Fortran 95:

```
call spgst(ap, bp [,itype] [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reduces real symmetric-definite generalized eigenproblems

$$A*x = \lambda*B*x, A*B*x = \lambda*x, \text{ or } B*A*x = \lambda*x$$

to the standard form $C*y = \lambda*y$, using packed matrix storage. Here A is a real symmetric matrix, and B is a real symmetric positive-definite matrix. Before calling this routine, call `?pptrf` to compute the Cholesky factorization: $B = U^T*U$ or $B = L*L^T$.

Input Parameters

<i>itype</i>	<p>INTEGER. Must be 1 or 2 or 3.</p> <p>If <i>itype</i> = 1, the generalized eigenproblem is $A*z = \lambda*B*z$</p> <p>for <i>uplo</i> = 'U': $C = \text{inv}(U^T)*A*\text{inv}(U)$, $z = \text{inv}(U)*y$;</p> <p>for <i>uplo</i> = 'L': $C = \text{inv}(L)*A*\text{inv}(L^T)$, $z = \text{inv}(L^T)*y$.</p> <p>If <i>itype</i> = 2, the generalized eigenproblem is $A*B*z = \lambda*z$</p> <p>for <i>uplo</i> = 'U': $C = U*A*U^T$, $z = \text{inv}(U)*y$;</p> <p>for <i>uplo</i> = 'L': $C = L^T*A*L$, $z = \text{inv}(L^T)*y$.</p> <p>If <i>itype</i> = 3, the generalized eigenproblem is $B*A*z = \lambda*z$</p> <p>for <i>uplo</i> = 'U': $C = U*A*U^T$, $z = U^T*y$;</p> <p>for <i>uplo</i> = 'L': $C = L^T*A*L$, $z = L*y$.</p>
<i>uplo</i>	<p>CHARACTER*1. <i>n</i>	<p>INTEGER. The order of the matrices A and B ($n \geq 0$).</p>
<i>ap, bp</i>	<p>REAL for <code>sspgst</code></p>

DOUBLE PRECISION for `dspgst`.

Arrays:

`ap(*)` contains the packed upper or lower triangle of A .

The dimension of `ap` must be at least $\max(1, n*(n+1)/2)$.

`bp(*)` contains the packed Cholesky factor of B (as returned by `?pptrf` with the same `uplo` value).

The dimension of `bp` must be at least $\max(1, n*(n+1)/2)$.

Output Parameters

<code>ap</code>	The upper or lower triangle of A is overwritten by the upper or lower triangle of C , as specified by the arguments <code>itype</code> and <code>uplo</code> .
<code>info</code>	INTEGER. If <code>info</code> = 0, the execution is successful. If <code>info</code> = $-i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spgst` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>bp</code>	Holds the array B of size $(n*(n+1)/2)$.
<code>itype</code>	Must be 1, 2, or 3. The default value is 1.
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

Forming the reduced matrix C is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if `itype` = 1) or B (if `itype` = 2 or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?hpgst

Reduces a complex Hermitian-definite generalized eigenvalue problem to the standard form using packed storage.

Syntax

FORTRAN 77:

```
call chpgst(itype, uplo, n, ap, bp, info)
call zhpgst(itype, uplo, n, ap, bp, info)
```

Fortran 95:

```
call hpgst(ap, bp [,itype] [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reduces real symmetric-definite generalized eigenproblems

$$A^*z = \lambda^*B^*z, A^*B^*z = \lambda^*z, \text{ or } B^*A^*z = \lambda^*z.$$

to the standard form $C^*y = \lambda^*y$, using packed matrix storage. Here A is a real symmetric matrix, and B is a real symmetric positive-definite matrix. Before calling this routine, you must call `?pptrf` to compute the Cholesky factorization: $B = U^H*U$ or $B = L*L^H$.

Input Parameters

itype INTEGER. Must be 1 or 2 or 3.
 If *itype* = 1, the generalized eigenproblem is $A^*z = \lambda^*B^*z$
 for *uplo* = 'U': $C = \text{inv}(U^H)*A*\text{inv}(U)$, $z = \text{inv}(U)*y$;
 for *uplo* = 'L': $C = \text{inv}(L)*A*\text{inv}(L^H)$, $z = \text{inv}(L^H)*y$.
 If *itype* = 2, the generalized eigenproblem is $A^*B^*z = \lambda^*z$
 for *uplo* = 'U': $C = U^H*A*U$, $z = \text{inv}(U)*y$;
 for *uplo* = 'L': $C = L^H*A*L$, $z = \text{inv}(L^H)*y$.
 If *itype* = 3, the generalized eigenproblem is $B^*A^*z = \lambda^*z$

for $uplo = 'U'$: $C = U^*A^*U^H$, $z = U^H*y$;
 for $uplo = 'L'$: $C = L^H*A*L$, $z = L*y$.
uplo CHARACTER*1. Must be 'U' or 'L'.
 If $uplo = 'U'$, *ap* stores the packed upper triangle of *A*;
 you must supply *B* in the factored form $B = U^H*U$.
 If $uplo = 'L'$, *ap* stores the packed lower triangle of *A*;
 you must supply *B* in the factored form $B = L*L^H$.
n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).
ap, bp COMPLEX for `chpgstDOUBLE` COMPLEX for `zhpgst`.
 Arrays:
ap(*) contains the packed upper or lower triangle of *A*.
 The dimension of *a* must be at least $\max(1, n*(n+1)/2)$.
bp(*) contains the packed Cholesky factor of *B* (as returned
 by `?pptrf` with the same *uplo* value).
 The dimension of *b* must be at least $\max(1, n*(n+1)/2)$.

Output Parameters

ap The upper or lower triangle of *A* is overwritten by the upper
 or lower triangle of *C*, as specified by the arguments *itype*
 and *uplo*.
info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpgst` interface are the following:

ap Holds the array *A* of size $(n*(n+1)/2)$.
bp Holds the array *B* of size $(n*(n+1)/2)$.
itype Must be 1, 2, or 3. The default value is 1.
uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

Forming the reduced matrix C is a stable procedure. However, it involves implicit multiplication by $\text{inv}(B)$ (if $\text{itype} = 1$) or B (if $\text{itype} = 2$ or 3). When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion.

The approximate number of floating-point operations is n^3 .

?sbgst

Reduces a real symmetric-definite generalized eigenproblem for banded matrices to the standard form using the factorization performed by ?pbstf.

Syntax

FORTRAN 77:

```
call ssgst(vect, uplo, n, ka, kb, ab, ldab, bb, ldbb, x, ldx, work, info)
call dsbgst(vect, uplo, n, ka, kb, ab, ldab, bb, ldbb, x, ldx, work, info)
```

Fortran 95:

```
call sbgst(ab, bb [,x] [,uplo] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

To reduce the real symmetric-definite generalized eigenproblem $A*z = \lambda*B*z$ to the standard form $C*y = \lambda*y$, where A , B and C are banded, this routine must be preceded by a call to `spb-stf/dpbstf`, which computes the split Cholesky factorization of the positive-definite matrix B : $B = S^T * S$. The split Cholesky factorization, compared with the ordinary Cholesky factorization, allows the work to be approximately halved.

This routine overwrites A with $C = X^T * A * X$, where $X = \text{inv}(S) * Q$ and Q is an orthogonal matrix chosen (implicitly) to preserve the bandwidth of A . The routine also has an option to allow the accumulation of X , and then, if z is an eigenvector of C , $X*z$ is an eigenvector of the original system.

Input Parameters

<i>vect</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>vect</i> = 'N', then matrix <i>x</i> is not returned; If <i>vect</i> = 'V', then matrix <i>x</i> is returned.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>ka</i>	INTEGER. The number of super- or sub-diagonals in <i>A</i> ($ka \geq 0$).
<i>kb</i>	INTEGER. The number of super- or sub-diagonals in <i>B</i> ($ka \geq kb \geq 0$).
<i>ab, bb, work</i>	REAL for <i>ssbgst</i> DOUBLE PRECISION for <i>dsbgst</i> <i>ab</i> (<i>ldab</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldbb</i> ,*) is an array containing the banded split Cholesky factor of <i>B</i> as specified by <i>uplo</i> , <i>n</i> and <i>kb</i> and returned by spbstf/dpbstf . The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array, dimension at least $\max(1, 2*n)$
<i>ldab</i>	INTEGER. The first dimension of the array <i>ab</i> ; must be at least $ka+1$.
<i>ldbb</i>	INTEGER. The first dimension of the array <i>bb</i> ; must be at least $kb+1$.
<i>ldx</i>	The first dimension of the output array <i>x</i> . Constraints: if <i>vect</i> = 'N', then $ldx \geq 1$; if <i>vect</i> = 'V', then $ldx \geq \max(1, n)$.

Output Parameters

<i>ab</i>	On exit, this array is overwritten by the upper or lower triangle of <i>C</i> as specified by <i>uplo</i> .
<i>x</i>	REAL for <i>ssbgst</i> DOUBLE PRECISION for <i>dsbgst</i> Array. If <i>vect</i> = 'V', then <i>x</i> (<i>ldx</i> ,*) contains the <i>n</i> -by- <i>n</i> matrix $X = \text{inv}(S)*Q$. If <i>vect</i> = 'N', then <i>x</i> is not referenced. The second dimension of <i>x</i> must be: at least $\max(1, n)$, if <i>vect</i> = 'V'; at least 1, if <i>vect</i> = 'N'.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sbgst* interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size (<i>ka</i> +1, <i>n</i>).
<i>bb</i>	Holds the array <i>B</i> of size (<i>kb</i> +1, <i>n</i>).
<i>x</i>	Holds the matrix <i>x</i> of size (<i>n</i> , <i>n</i>).
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vect</i>	Restored based on the presence of the argument <i>x</i> as follows: <i>vect</i> = 'V', if <i>x</i> is present, <i>vect</i> = 'N', if <i>x</i> is omitted.

Application Notes

Forming the reduced matrix *C* involves implicit multiplication by $\text{inv}(B)$. When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if *B* is ill-conditioned with respect to inversion.

If ka and kb are much less than n then the total number of floating-point operations is approximately $6n^2*kb$, when $vect = 'N'$. Additional $(3/2)n^3*(kb/ka)$ operations are required when $vect = 'V'$.

?hbgst

Reduces a complex Hermitian-definite generalized eigenproblem for banded matrices to the standard form using the factorization performed by `?pbstf`.

Syntax

FORTRAN 77:

```
call chbgst(vect, uplo, n, ka, kb, ab, ldab, bb, ldbb, x, ldx, work, rwork, info)
```

```
call zhbgst(vect, uplo, n, ka, kb, ab, ldab, bb, ldbb, x, ldx, work, rwork, info)
```

Fortran 95:

```
call hbgst(ab, bb [,x] [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

To reduce the complex Hermitian-definite generalized eigenproblem $A*z = \lambda*B*z$ to the standard form $C*x = \lambda*y$, where A , B and C are banded, this routine must be preceded by a call to `cpbstf/zpbstf`, which computes the split Cholesky factorization of the positive-definite matrix B : $B = S^H*S$. The split Cholesky factorization, compared with the ordinary Cholesky factorization, allows the work to be approximately halved.

This routine overwrites A with $C = X^H*A*X$, where $X = \text{inv}(S)*Q$, and Q is a unitary matrix chosen (implicitly) to preserve the bandwidth of A . The routine also has an option to allow the accumulation of X , and then, if z is an eigenvector of C , $X*z$ is an eigenvector of the original system.

Input Parameters

`vect` CHARACTER*1. Must be 'N' or 'V'.

	<p>If <i>vect</i> = 'N', then matrix <i>x</i> is not returned; If <i>vect</i> = 'V', then matrix <i>x</i> is returned.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ab</i> stores the upper triangular part of <i>A</i>. If <i>uplo</i> = 'L', <i>ab</i> stores the lower triangular part of <i>A</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).</p>
<i>ka</i>	<p>INTEGER. The number of super- or sub-diagonals in <i>A</i> ($ka \geq 0$).</p>
<i>kb</i>	<p>INTEGER. The number of super- or sub-diagonals in <i>B</i> ($ka \geq kb \geq 0$).</p>
<i>ab, bb, work</i>	<p>COMPLEX for <code>chbgst</code> DOUBLE COMPLEX for <code>zhbgst</code> <i>ab</i> (<i>ldab</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> (as specified by <i>uplo</i>) in band storage format. The second dimension of the array <i>ab</i> must be at least $\max(1, n)$. <i>bb</i> (<i>ldbb</i>,*) is an array containing the banded split Cholesky factor of <i>B</i> as specified by <i>uplo</i>, <i>n</i> and <i>kb</i> and returned by cpbstf/zpbstf. The second dimension of the array <i>bb</i> must be at least $\max(1, n)$. <i>work</i>(*) is a workspace array, dimension at least $\max(1, n)$</p>
<i>ldab</i>	<p>INTEGER. The first dimension of the array <i>ab</i>; must be at least $ka+1$.</p>
<i>ldbb</i>	<p>INTEGER. The first dimension of the array <i>bb</i>; must be at least $kb+1$.</p>
<i>ldx</i>	<p>The first dimension of the output array <i>x</i>. Constraints: if <i>vect</i> = 'N', then $ldx \geq 1$; if <i>vect</i> = 'V', then $ldx \geq \max(1, n)$.</p>
<i>rwork</i>	<p>REAL for <code>chbgst</code> DOUBLE PRECISION for <code>zhbgst</code> Workspace array, dimension at least $\max(1, n)$</p>

Output Parameters

<i>ab</i>	On exit, this array is overwritten by the upper or lower triangle of C as specified by <i>uplo</i> .
<i>x</i>	COMPLEX for <i>chbgst</i> DOUBLE COMPLEX for <i>zhbgst</i> Array. If <i>vect</i> = 'V', then $x(ldx,*)$ contains the n -by- n matrix $X = inv(S)*Q$. If <i>vect</i> = 'N', then x is not referenced. The second dimension of x must be: at least $\max(1, n)$, if <i>vect</i> = 'V'; at least 1, if <i>vect</i> = 'N'.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = $-i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *hbgst* interface are the following:

<i>ab</i>	Holds the array A of size $(ka+1, n)$.
<i>bb</i>	Holds the array B of size $(kb+1, n)$.
<i>x</i>	Holds the matrix X of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vect</i>	Restored based on the presence of the argument x as follows: <i>vect</i> = 'V', if x is present, <i>vect</i> = 'N', if x is omitted.

Application Notes

Forming the reduced matrix C involves implicit multiplication by $inv(B)$. When the routine is used as a step in the computation of eigenvalues and eigenvectors of the original problem, there may be a significant loss of accuracy if B is ill-conditioned with respect to inversion. The total number of floating-point operations is approximately $20n^2*kb$, when *vect* = 'N'. Additional $5n^3*(kb/ka)$ operations are required when *vect* = 'V'. All these estimates assume that both ka and kb are much less than n .

?pbstf

Computes a split Cholesky factorization of a real symmetric or complex Hermitian positive-definite banded matrix used in ?sbgst/?hbgst .

Syntax

FORTRAN 77:

```
call spbstf(uplo, n, kb, bb, ldbb, info)
call dpbstf(uplo, n, kb, bb, ldbb, info)
call cpbstf(uplo, n, kb, bb, ldbb, info)
call zpbstf(uplo, n, kb, bb, ldbb, info)
```

Fortran 95:

```
call pbstf(bb [, uplo] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes a split Cholesky factorization of a real symmetric or complex Hermitian positive-definite band matrix B . It is to be used in conjunction with `?sbgst/?hbgst`.

The factorization has the form $B = S^T * S$ (or $B = S^H * S$ for complex flavors), where S is a band matrix of the same bandwidth as B and the following structure: S is upper triangular in the first $(n+kb)/2$ rows and lower triangular in the remaining rows.

Input Parameters

<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'. If <code>uplo = 'U'</code> , <code>bb</code> stores the upper triangular part of B . If <code>uplo = 'L'</code> , <code>bb</code> stores the lower triangular part of B .
<code>n</code>	INTEGER. The order of the matrix B ($n \geq 0$).
<code>kb</code>	INTEGER. The number of super- or sub-diagonals in B ($kb \geq 0$).
<code>bb</code>	REAL for <code>spbstf</code> DOUBLE PRECISION for <code>dpbstf</code>

COMPLEX for `cpbstf`
 DOUBLE COMPLEX for `zpbstf`.
bb (*ldb*,*) is an array containing either upper or lower triangular part of the matrix *B* (as specified by *uplo*) in band storage format.
 The second dimension of the array *bb* must be at least $\max(1, n)$.

ldb INTEGER. The first dimension of *bb*; must be at least $kb+1$.

Output Parameters

bb On exit, this array is overwritten by the elements of the split Cholesky factor *S*.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = *i*, then the factorization could not be completed, because the updated element b_{ii} would be the square root of a negative number; hence the matrix *B* is not positive-definite.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `pbstf` interface are the following:

bb Holds the array *B* of size $(kb+1, n)$.
uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed factor *S* is the exact factor of a perturbed matrix $B + E$, where

$$|E| \leq c(kb + 1)\epsilon \|S^H\| |S|, \quad |e_{ij}| \leq c(kb + 1)\epsilon \sqrt{b_{ii}b_{jj}}$$

$c(n)$ is a modest linear function of n , and ε is the machine precision.

The total number of floating-point operations for real flavors is approximately $n(kb+1)^2$. The number of operations for complex flavors is 4 times greater. All these estimates assume that kb is much less than n .

After calling this routine, you can call [?sbgst/?hbgst](#) to solve the generalized eigenproblem $Az = \lambda Bz$, where A and B are banded and B is positive-definite.

Nonsymmetric Eigenvalue Problems

This section describes LAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

A *nonsymmetric eigenvalue problem* is as follows: given a nonsymmetric (or non-Hermitian) matrix A , find the *eigenvalues* λ and the corresponding *eigenvectors* z that satisfy the equation

$$Az = \lambda z \text{ (right eigenvectors } z)$$

or the equation

$$z^H A = \lambda z^H \text{ (left eigenvectors } z).$$

Nonsymmetric eigenvalue problems have the following properties:

- The number of eigenvectors may be less than the matrix order (but is not less than the number of *distinct eigenvalues* of A).
- Eigenvalues may be complex even for a real matrix A .
- If a real nonsymmetric matrix has a complex eigenvalue $a+bi$ corresponding to an eigenvector z , then $a-bi$ is also an eigenvalue. The eigenvalue $a-bi$ corresponds to the eigenvector whose elements are complex conjugate to the elements of z .

To solve a nonsymmetric eigenvalue problem with LAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained. [Table 4-5](#) lists LAPACK routines (FORTRAN 77 interface) for reducing the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation $A = QHQ^H$ as well as routines for solving eigenvalue problems with Hessenberg matrices, forming the Schur factorization of such matrices and computing the corresponding condition numbers. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Decision tree in [Figure 4-4](#) helps you choose the right routine or sequence of routines for an eigenvalue problem with a real nonsymmetric matrix. If you need to solve an eigenvalue problem with a complex non-Hermitian matrix, use the decision tree shown in [Figure 4-5](#) .

Figure 4-4 Decision Tree: Real Nonsymmetric Eigenvalue Problems

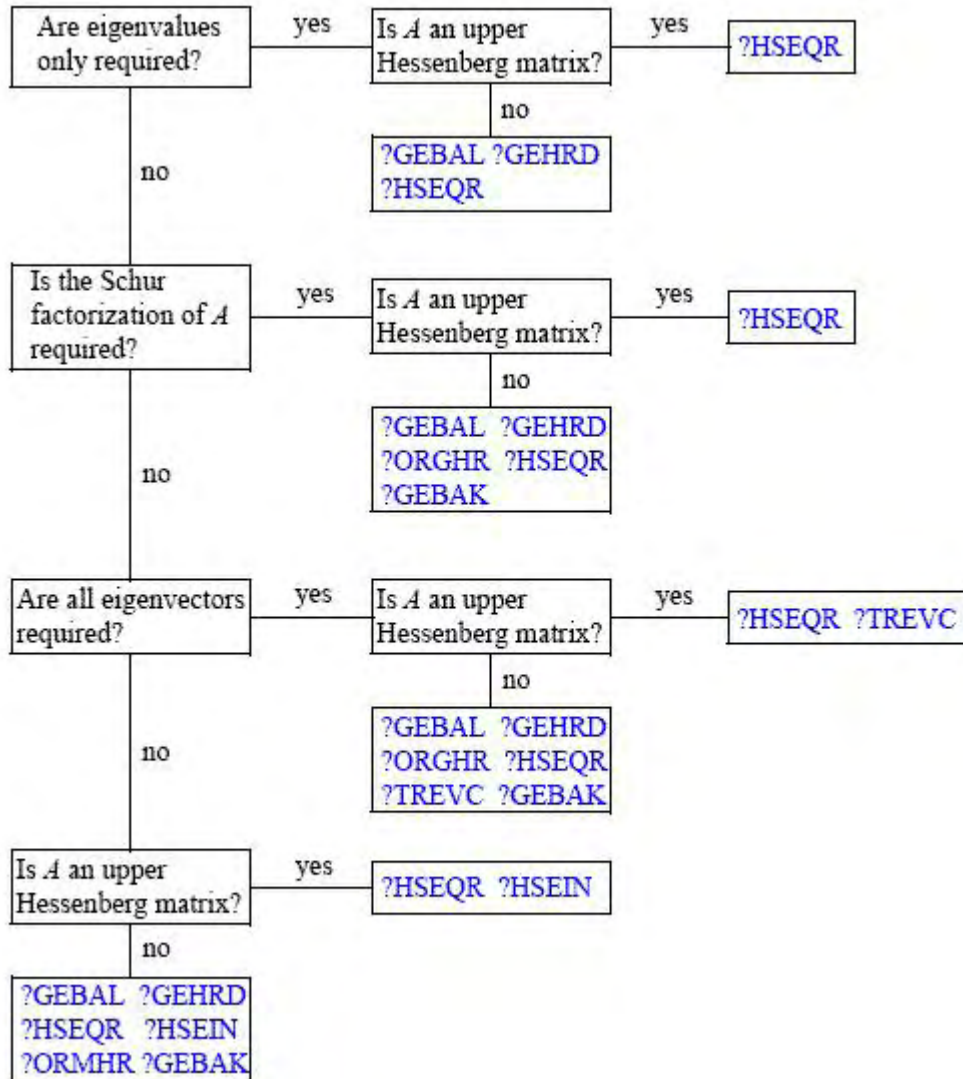

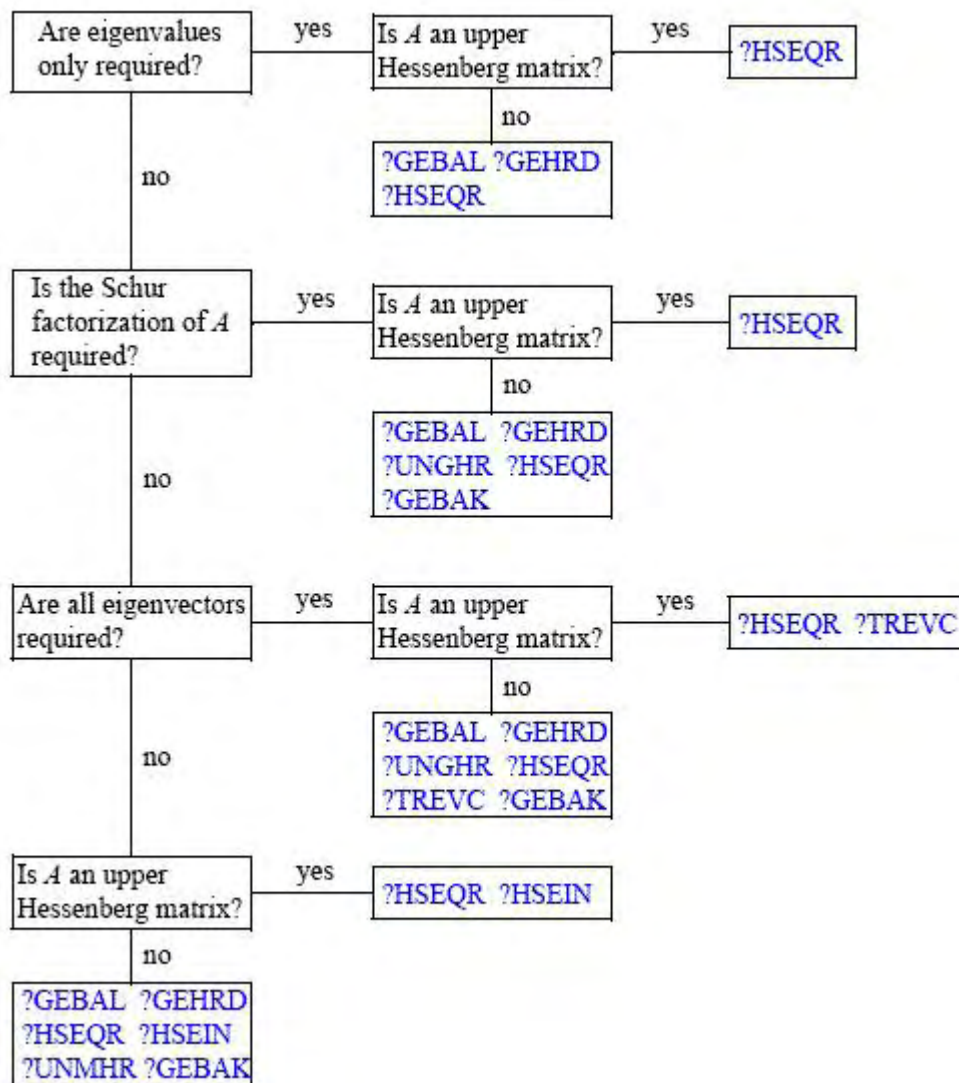

Figure 4-5 Decision Tree: Complex Non-Hermitian Eigenvalue Problems

?gehrd

Reduces a general matrix to upper Hessenberg form.

Syntax

FORTRAN 77:

```
call sgehrd(n, ilo, ihi, a, lda, tau, work, lwork, info)
call dgehrd(n, ilo, ihi, a, lda, tau, work, lwork, info)
call cgehrd(n, ilo, ihi, a, lda, tau, work, lwork, info)
call zgehrd(n, ilo, ihi, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call gehrd(a [, tau] [,ilo] [,ihi] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reduces a general matrix A to upper Hessenberg form H by an orthogonal or unitary similarity transformation $A = Q^*H^*Q^H$. Here H has real subdiagonal elements.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of *elementary reflectors*. Routines are provided to work with Q in this representation.

Input Parameters

n	INTEGER. The order of the matrix A ($n \geq 0$).
ilo, ihi	INTEGER. If A is an output by ?gebal, then ilo and ihi must contain the values returned by that routine. Otherwise $ilo = 1$ and $ihi = n$. (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, $ilo = 1$ and $ihi = 0$.)
$a, work$	REAL for sgehrd DOUBLE PRECISION for dgehrd COMPLEX for cgehrd DOUBLE COMPLEX for zgehrd. Arrays:

a (*lda*,*) contains the matrix *A*.
The second dimension of *a* must be at least $\max(1, n)$.
work (*lwork*) is a workspace array.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

lwork INTEGER. The size of the *work* array; at least $\max(1, n)$.
If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#).
See *Application Notes* for the suggested value of *lwork*.

Output Parameters

a Overwritten by the upper Hessenberg matrix *H* and details of the matrix *Q*. The subdiagonal elements of *H* are real.

tau REAL for *sgehrd*
DOUBLE PRECISION for *dgehrd*
COMPLEX for *cgehrd*
DOUBLE COMPLEX for *zgehrd*.
Array, DIMENSION at least $\max(1, n-1)$.
Contains additional information on the matrix *Q*.

work(1) If *info* = 0, on exit *work*(1) contains the minimum value of *lwork* required for optimum performance. Use this *lwork* for subsequent runs.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gehrd* interface are the following:

a Holds the matrix *A* of size (*n*,*n*).

tau Holds the vector of length (*n*-1).

ilo Default value for this argument is *ilo* = 1.

ihi Default value for this argument is $ihi = n$.

Application Notes

For better performance, try using $lwork = n * blocksize$, where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed Hessenberg matrix *H* is exactly similar to a nearby matrix $A + E$, where $\|E\|_2 < c(n)\epsilon \|A\|_2$, $c(n)$ is a modestly increasing function of n , and ϵ is the machine precision.

The approximate number of floating-point operations for real flavors is $(2/3) * (ihi - ilo)^2 (2ihi + 2ilo + 3n)$; for complex flavors it is 4 times greater.

?orghr

Generates the real orthogonal matrix Q determined by ?gehrd.

Syntax

FORTRAN 77:

```
call sorghr(n, ilo, ihi, a, lda, tau, work, lwork, info)
call dorghr(n, ilo, ihi, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call orghr(a, tau [,ilo] [,ihi] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine explicitly generates the orthogonal matrix Q that has been determined by a preceding call to `sgehrd/dgehrd`. (The routine `?gehrd` reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation, $A = Q^*H^*Q^T$, and represents the matrix Q as a product of *ihi-ilo elementary reflectors*. Here *ilo* and *ihi* are values determined by `sgebal/dgebal` when balancing the matrix; if the matrix has not been balanced, *ilo* = 1 and *ihi* = *n*.)

The matrix Q generated by `?orghr` has the structure:

$$Q = \begin{bmatrix} I & 0 & 0 \\ 0 & Q_{22} & 0 \\ 0 & 0 & I \end{bmatrix}$$

where Q_{22} occupies rows and columns *ilo* to *ihi*.

Input Parameters

<i>n</i>	INTEGER. The order of the matrix Q ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to <code>?gehrd</code> . (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, <i>ilo</i> = 1 and <i>ihi</i> = 0.)
<i>a, tau, work</i>	REAL for <code>sorghr</code> DOUBLE PRECISION for <code>dorghr</code> Arrays: <i>a(lda,*)</i> contains details of the vectors which define the elementary reflectors, as returned by <code>?gehrd</code> . The second dimension of <i>a</i> must be at least $\max(1, n)$.

$\tau(*)$ contains further details of the elementary reflectors, as returned by `?gghrd`.
 The dimension of τ must be at least $\max(1, n-1)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda INTEGER. The first dimension of a ; at least $\max(1, n)$.
lwork INTEGER. The size of the $work$ array;
 $lwork \geq \max(1, ihi-ilo)$.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.
 See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a Overwritten by the n -by- n orthogonal matrix Q .
 $work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.
info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `orghr` interface are the following:

a Holds the matrix A of size (n, n) .
 τ Holds the vector of length $(n-1)$.
 ilo Default value for this argument is $ilo = 1$.
 ihi Default value for this argument is $ihi = n$.

Application Notes

For better performance, try using $lwork = (ihi - ilo) * blocksize$ where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from the exact result by a matrix E such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of floating-point operations is $(4/3)(ihi - ilo)^3$.

The complex counterpart of this routine is [?unghr](#).

?ormhr

Multiplies an arbitrary real matrix C by the real orthogonal matrix Q determined by ?gehrd.

Syntax

FORTRAN 77:

```
call sormhr(side, trans, m, n, ilo, ihi, a, lda, tau, c, ldc, work, lwork,
info)

call dormhr(side, trans, m, n, ilo, ihi, a, lda, tau, c, ldc, work, lwork,
info)
```

Fortran 95:

```
call ormhr(a, tau, c [,ilo] [,ihi] [,side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a matrix C by the orthogonal matrix Q that has been determined by a preceding call to `sgehrd/dgehrd`. (The routine `?gehrd` reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation, $A = Q^T H Q$, and represents the matrix Q as a product of $ihi-ilo$ elementary reflectors. Here ilo and ihi are values determined by `sgebal/dgebal` when balancing the matrix; if the matrix has not been balanced, $ilo = 1$ and $ihi = n$.)

With `?ormhr`, you can form one of the matrix products $Q^T C$, $Q C$, $C^T Q$, or $C Q^T$, overwriting the result on C (which may be any real rectangular matrix).

A common application of `?ormhr` is to transform a matrix V of eigenvectors of H to the matrix QV of eigenvectors of A .

Input Parameters

<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', then the routine forms $Q^T C$ or $Q C$. If <i>side</i> = 'R', then the routine forms $C^T Q$ or $C Q^T$.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'T'. If <i>trans</i> = 'N', then Q is applied to C . If <i>trans</i> = 'T', then Q^T is applied to C .
<i>m</i>	INTEGER. The number of rows in C ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns in C ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to <code>?gehrd</code> . If $m > 0$ and <i>side</i> = 'L', then $1 \leq ilo \leq ihi \leq m$. If $m = 0$ and <i>side</i> = 'L', then $ilo = 1$ and $ihi = 0$. If $n > 0$ and <i>side</i> = 'R', then $1 \leq ilo \leq ihi \leq n$. If $n = 0$ and <i>side</i> = 'R', then $ilo = 1$ and $ihi = 0$.
<i>a, tau, c, work</i>	REAL for <code>sormhr</code>

DOUBLE PRECISION for dormhr

Arrays:

$a(lda,*)$ contains details of the vectors which define the *elementary reflectors*, as returned by ?gehrd.

The second dimension of a must be at least $\max(1, m)$ if $side = 'L'$ and at least $\max(1, n)$ if $side = 'R'$.

$tau(*)$ contains further details of the *elementary reflectors*, as returned by ?gehrd .

The dimension of tau must be at least $\max(1, m-1)$ if $side = 'L'$ and at least $\max(1, n-1)$ if $side = 'R'$.

$c(ldc,*)$ contains the m by n matrix C . The second dimension of c must be at least $\max(1, n)$.

$work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of a ; at least $\max(1, m)$ if $side = 'L'$ and at least $\max(1, n)$ if $side = 'R'$.

ldc INTEGER. The first dimension of c ; at least $\max(1, m)$.

$lwork$ INTEGER. The size of the $work$ array.

If $side = 'L'$, $lwork \geq \max(1, n)$.

If $side = 'R'$, $lwork \geq \max(1, m)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by xerbla.

See *Application Notes* for the suggested value of $lwork$.

Output Parameters

c c is overwritten by product $Q*C$, Q^T*C , $C*Q$, or $C*Q^T$ as specified by $side$ and $trans$.

$work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$ INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ormhr` interface are the following:

<code>a</code>	Holds the matrix A of size (r, r) . $r = m$ if <code>side = 'L'</code> . $r = n$ if <code>side = 'R'</code> .
<code>tau</code>	Holds the vector of length $(r-1)$.
<code>c</code>	Holds the matrix C of size (m, n) .
<code>ilo</code>	Default value for this argument is <code>ilo = 1</code> .
<code>ihi</code>	Default value for this argument is <code>ihi = n</code> .
<code>side</code>	Must be 'L' or 'R'. The default value is 'L'.
<code>trans</code>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

For better performance, `lwork` should be at least $n * \text{blocksize}$ if `side = 'L'` and at least $m * \text{blocksize}$ if `side = 'R'`, where `blocksize` is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from the exact result by a matrix E such that $\|E\|_2 = O(\epsilon) \|C\|_2$, where ϵ is the machine precision.

The approximate number of floating-point operations is

$2n(ihi-ilo)^2$ if *side* = 'L';

$2m(ihi-ilo)^2$ if *side* = 'R'.

The complex counterpart of this routine is [?unmhr](#).

?unghr

Generates the complex unitary matrix *Q* determined by [?gehrd](#).

Syntax

FORTRAN 77:

```
call cunghr(n, ilo, ihi, a, lda, tau, work, lwork, info)
```

```
call zunghr(n, ilo, ihi, a, lda, tau, work, lwork, info)
```

Fortran 95:

```
call unghr(a, tau [,ilo] [,ihi] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine is intended to be used following a call to `cgehrd/zgehrd`, which reduces a complex matrix *A* to upper Hessenberg form *H* by a unitary similarity transformation: $A = Q^*H^*Q^H$.

`?gehrd` represents the matrix *Q* as a product of *ihi-ilo* *elementary reflectors*. Here *ilo* and *ihi* are values determined by `cgebal/zgebal` when balancing the matrix; if the matrix has not been balanced, *ilo* = 1 and *ihi* = *n*.

Use the routine [?unghr](#) to generate *Q* explicitly as a square matrix. The matrix *Q* has the structure:

$$Q = \begin{bmatrix} I & 0 & 0 \\ 0 & Q_{22} & 0 \\ 0 & 0 & I \end{bmatrix}$$

where Q_{22} occupies rows and columns ilo to ihi .

Input Parameters

n INTEGER. The order of the matrix Q ($n \geq 0$).

ilo, ihi INTEGER. These must be the same parameters ilo and ihi , respectively, as supplied to `?gehrd`. (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$. If $n = 0$, then $ilo = 1$ and $ihi = 0$.)

$a, tau, work$ COMPLEX for `cunghr`
DOUBLE COMPLEX for `zunghr`.

Arrays:
 $a(lda,*)$ contains details of the vectors which define the *elementary reflectors*, as returned by `?gehrd`.
 The second dimension of a must be at least $\max(1, n)$.
 $tau(*)$ contains further details of the *elementary reflectors*, as returned by `?gehrd`.
 The dimension of tau must be at least $\max(1, n-1)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of a ; at least $\max(1, n)$.

$lwork$ INTEGER. The size of the $work$ array;
 $lwork \geq \max(1, ihi-ilo)$.
 If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`.
 See *Application Notes* for the suggested value of $lwork$.

Output Parameters

a Overwritten by the n -by- n unitary matrix Q .

$work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$ INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unghr` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>tau</code>	Holds the vector of length $(n-1)$.
<code>ilo</code>	Default value for this argument is $ilo = 1$.
<code>ihi</code>	Default value for this argument is $ihi = n$.

Application Notes

For better performance, try using $lwork = (ihi-ilo)*blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run, or set $lwork = -1$.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from the exact result by a matrix E such that $\|E\|_2 = O(\epsilon)$, where ϵ is the machine precision.

The approximate number of real floating-point operations is $(16/3)(ihi-ilo)^3$.

The real counterpart of this routine is [?orghr](#).

?unmhr

Multiplies an arbitrary complex matrix C by the complex unitary matrix Q determined by ?gehrd.

Syntax

FORTRAN 77:

```
call cunmhr(side, trans, m, n, ilo, ihi, a, lda, tau, c, ldc, work, lwork, info)
```

```
call zunmhr(side, trans, m, n, ilo, ihi, a, lda, tau, c, ldc, work, lwork, info)
```

Fortran 95:

```
call unmhr(a, tau, c [,ilo] [,ihi] [,side] [,trans] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine multiplies a matrix C by the unitary matrix Q that has been determined by a preceding call to `cgehrd/zgehrd`. (The routine `?gehrd` reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation, $A = Q^H H Q$, and represents the matrix Q as a product of $ihi-ilo$ elementary reflectors. Here ilo and ihi are values determined by `cgebal/zgebal` when balancing the matrix; if the matrix has not been balanced, $ilo = 1$ and $ihi = n$.)

With `?unmhr`, you can form one of the matrix products $Q^H C$, $Q^H C$, $C^H Q$, or $C^H Q^H$, overwriting the result on C (which may be any complex rectangular matrix). A common application of this routine is to transform a matrix V of eigenvectors of H to the matrix QV of eigenvectors of A .

Input Parameters

<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', then the routine forms $Q^H C$ or $Q^H C$. If <i>side</i> = 'R', then the routine forms $C^H Q$ or $C^H Q^H$.
<i>trans</i>	CHARACTER*1. Must be 'N' or 'C'. If <i>trans</i> = 'N', then Q is applied to C . If <i>trans</i> = 'T', then Q^H is applied to C .

m INTEGER. The number of rows in *c* ($m \geq 0$).

n INTEGER. The number of columns in *c* ($n \geq 0$).

ilo, ihi INTEGER. These must be the same parameters *ilo* and *ihi*, respectively, as supplied to `?gehrd`.
 If $m > 0$ and *side* = 'L', then $1 \leq ilo \leq ihi \leq m$.
 If $m = 0$ and *side* = 'L', then *ilo* = 1 and *ihi* = 0.
 If $n > 0$ and *side* = 'R', then $1 \leq ilo \leq ihi \leq n$.
 If $n = 0$ and *side* = 'R', then *ilo* = 1 and *ihi* = 0.

a, tau, c, work COMPLEX for `cunmhr`
 DOUBLE COMPLEX for `zunmhr`.
 Arrays:
a (*lda*,*) contains details of the vectors which define the elementary reflectors, as returned by `?gehrd`.
 The second dimension of *a* must be at least $\max(1, m)$ if *side* = 'L' and at least $\max(1, n)$ if *side* = 'R'.
tau(*) contains further details of the elementary reflectors, as returned by `?gehrd`.
 The dimension of *tau* must be at least $\max(1, m-1)$ if *side* = 'L' and at least $\max(1, n-1)$ if *side* = 'R'.
c (*ldc*,*) contains the *m*-by-*n* matrix *C*. The second dimension of *c* must be at least $\max(1, n)$.
work is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, m)$ if *side* = 'L' and at least $\max(1, n)$ if *side* = 'R'.

ldc INTEGER. The first dimension of *c*; at least $\max(1, m)$.

lwork INTEGER. The size of the *work* array.
 If *side* = 'L', $lwork \geq \max(1, n)$.
 If *side* = 'R', $lwork \geq \max(1, m)$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by `xerbla`. See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>c</i>	<i>c</i> is overwritten by Q^*C , or Q^H*C , or $C*Q^H$, or $C*Q$ as specified by <i>side</i> and <i>trans</i> .
<i>work(1)</i>	If <i>info</i> = 0, on exit <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `unmhr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>r</i> , <i>r</i>). <i>r</i> = <i>m</i> if <i>side</i> = 'L'. <i>r</i> = <i>n</i> if <i>side</i> = 'R'.
<i>tau</i>	Holds the vector of length (<i>r</i> -1).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>side</i>	Must be 'L' or 'R'. The default value is 'L'.
<i>trans</i>	Must be 'N' or 'C'. The default value is 'N'.

Application Notes

For better performance, *lwork* should be at least $n*blocksize$ if *side* = 'L' and at least $m*blocksize$ if *side* = 'R', where *blocksize* is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1 , then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The computed matrix Q differs from the exact result by a matrix E such that $\|E\|_2 = O(\epsilon) * \|C\|_2$, where ϵ is the machine precision.

The approximate number of floating-point operations is

$8n(ihi-ilo)^2$ if $side = 'L'$;

$8m(ihi-ilo)^2$ if $side = 'R'$.

The real counterpart of this routine is [?ormhr](#).

?gebal

Balances a general matrix to improve the accuracy of computed eigenvalues and eigenvectors.

Syntax

FORTRAN 77:

```
call sgebal(job, n, a, lda, ilo, ihi, scale, info)
call dgebal(job, n, a, lda, ilo, ihi, scale, info)
call cgebal(job, n, a, lda, ilo, ihi, scale, info)
call zgebal(job, n, a, lda, ilo, ihi, scale, info)
```

Fortran 95:

```
call gebal(a [, scale] [,ilo] [,ihi] [,job] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine *balances* a matrix A by performing either or both of the following two similarity transformations:

(1) The routine first attempts to permute A to block upper triangular form:

$$PAP^T = A' = \begin{bmatrix} A'_{11} & A'_{12} & A'_{13} \\ 0 & A'_{22} & A'_{23} \\ 0 & 0 & A'_{33} \end{bmatrix}$$

where P is a permutation matrix, and A'_{11} and A'_{33} are upper triangular. The diagonal elements of A'_{11} and A'_{33} are eigenvalues of A . The rest of the eigenvalues of A are the eigenvalues of the central diagonal block A'_{22} , in rows and columns ilo to ihi . Subsequent operations to compute the eigenvalues of A (or its Schur factorization) need only be applied to these rows and columns; this can save a significant amount of work if $ilo > 1$ and $ihi < n$.

If no suitable permutation exists (as is often the case), the routine sets $ilo = 1$ and $ihi = n$, and A'_{22} is the whole of A .

(2) The routine applies a diagonal similarity transformation to A' , to make the rows and columns of A'_{22} as close in norm as possible:

$$A'' = DA'D^{-1} = \begin{bmatrix} I & 0 & 0 \\ 0 & D_{22} & 0 \\ 0 & 0 & I \end{bmatrix} \times \begin{bmatrix} A'_{11} & A'_{12} & A'_{13} \\ 0 & A'_{22} & A'_{23} \\ 0 & 0 & A'_{33} \end{bmatrix} \times \begin{bmatrix} I & 0 & 0 \\ 0 & D_{22}^{-1} & 0 \\ 0 & 0 & I \end{bmatrix}$$

This scaling can reduce the norm of the matrix (that is, $\|A'_{22}\| < \|A'_{22}\|$), and hence reduce the effect of rounding errors on the accuracy of computed eigenvalues and eigenvectors.

Input Parameters

job

CHARACTER*1. Must be 'N' or 'P' or 'S' or 'B'.

If *job* = 'N', then A is neither permuted nor scaled (but *ilo*, *ihi*, and *scale* get their values).

If *job* = 'P', then A is permuted but not scaled.

If *job* = 'S', then A is scaled but not permuted.

If *job* = 'B', then A is both scaled and permuted.

n INTEGER. The order of the matrix A ($n \geq 0$).

a REAL for sgebal
 DOUBLE PRECISION for dgebal
 COMPLEX for cgebal
 DOUBLE COMPLEX for zgebal.
 Arrays:
a (*lda*,*) contains the matrix A .
 The second dimension of *a* must be at least $\max(1, n)$. *a* is not referenced if *job* = 'N'.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

Output Parameters

a Overwritten by the balanced matrix (*a* is not referenced if *job* = 'N').

ilo, ihi INTEGER. The values *ilo* and *ihi* such that on exit $a(i, j)$ is zero if $i > j$ and $1 \leq j < ilo$ or $ihi < i \leq n$.
 If *job* = 'N' or 'S', then *ilo* = 1 and *ihi* = *n*.

scale REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors
 Array, DIMENSION at least $\max(1, n)$.
 Contains details of the permutations and scaling factors.
 More precisely, if p_j is the index of the row and column interchanged with row and column j , and d_j is the scaling factor used to balance row and column j , then
 $scale(j) = p_j$ for $j = 1, 2, \dots, ilo-1, ihi+1, \dots, n$;
 $scale(j) = d_j$ for $j = ilo, ilo + 1, \dots, ihi$.
 The order in which the interchanges are made is *n* to *ihi*+1, then 1 to *ilo*-1.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gebak` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>scale</code>	Holds the vector of length n .
<code>ilo</code>	Default value for this argument is $ilo = 1$.
<code>ihi</code>	Default value for this argument is $ihi = n$.
<code>job</code>	Must be 'B', 'S', 'P', or 'N'. The default value is 'B'.

Application Notes

The errors are negligible, compared with those in subsequent computations.

If the matrix A is balanced by this routine, then any eigenvectors computed subsequently are eigenvectors of the matrix A^{-1} and hence you must call `?gebak` to transform them back to eigenvectors of A .

If the Schur vectors of A are required, do not call this routine with `job = 'S'` or `'B'`, because then the balancing transformation is not orthogonal (not unitary for complex flavors).

If you call this routine with `job = 'P'`, then any Schur vectors computed subsequently are Schur vectors of the matrix A^{-1} , and you need to call `?gebak` (with `side = 'R'`) to transform them back to Schur vectors of A .

The total number of floating-point operations is proportional to n^2 .

?gebak

Transforms eigenvectors of a balanced matrix to those of the original nonsymmetric matrix.

Syntax

FORTRAN 77:

```
call sgebak(job, side, n, ilo, ihi, scale, m, v, ldv, info)
call dgebak(job, side, n, ilo, ihi, scale, m, v, ldv, info)
call cgebak(job, side, n, ilo, ihi, scale, m, v, ldv, info)
```

```
call zgebak(job, side, n, ilo, ihi, scale, m, v, ldv, info)
```

Fortran 95:

```
call gebak(v, scale [,ilo] [,ihi] [,job] [,side] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine is intended to be used after a matrix A has been balanced by a call to `?gebal`, and eigenvectors of the balanced matrix A'_{22} have subsequently been computed. For a description of balancing, see `?gebal`. The balanced matrix A'_{22} is obtained as $A'_{22} = D * P * A * P^T * \text{inv}(D)$, where P is a permutation matrix and D is a diagonal scaling matrix. This routine transforms the eigenvectors as follows:

if x is a right eigenvector of A'_{22} , then $P^T * \text{inv}(D) * x$ is a right eigenvector of A ; if x is a left eigenvector of A'_{22} , then $P^T * D * x$ is a left eigenvector of A .

Input Parameters

<i>job</i>	CHARACTER*1. Must be 'N' or 'P' or 'S' or 'B'. The same parameter <i>job</i> as supplied to <code>?gebal</code> .
<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', then left eigenvectors are transformed. If <i>side</i> = 'R', then right eigenvectors are transformed.
<i>n</i>	INTEGER. The number of rows of the matrix of eigenvectors ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. The values <i>ilo</i> and <i>ihi</i> , as returned by <code>?gebal</code> . (If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, then $ilo = 1$ and $ihi = 0$.)
<i>scale</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors Array, DIMENSION at least $\max(1, n)$. Contains details of the permutations and/or the scaling factors used to balance the original general matrix, as returned by <code>?gebal</code> .
<i>m</i>	INTEGER. The number of columns of the matrix of eigenvectors ($m \geq 0$).

v REAL for sgebak
 DOUBLE PRECISION for dgebak
 COMPLEX for cgebak
 DOUBLE COMPLEX for zgebak.
 Arrays:
v (*ldv*,*) contains the matrix of left or right eigenvectors to be transformed.
 The second dimension of *v* must be at least $\max(1, m)$.

ldv INTEGER. The first dimension of *v*; at least $\max(1, n)$.

Output Parameters

v Overwritten by the transformed eigenvectors.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gebak* interface are the following:

v Holds the matrix *v* of size (*n*,*m*).

scale Holds the vector of length *n*.

ilo Default value for this argument is *ilo* = 1.

ihi Default value for this argument is *ihi* = *n*.

job Must be 'B', 'S', 'P', or 'N'. The default value is 'B'.

side Must be 'L' or 'R'. The default value is 'L'.

Application Notes

The errors in this routine are negligible.

The approximate number of floating-point operations is approximately proportional to $m*n$.

?hseqr

Computes all eigenvalues and (optionally) the Schur factorization of a matrix reduced to Hessenberg form.

Syntax

FORTRAN 77:

```
call shseqr(job, compz, n, ilo, ihi, h, ldh, wr, wi, z, ldz, work, lwork,
info)
call dhseqr(job, compz, n, ilo, ihi, h, ldh, wr, wi, z, ldz, work, lwork,
info)
call chseqr(job, compz, n, ilo, ihi, h, ldh, w, z, ldz, work, lwork, info)
call zhseqr(job, compz, n, ilo, ihi, h, ldh, w, z, ldz, work, lwork, info)
```

Fortran 95:

```
call hseqr(h, wr, wi [,ilo] [,ihi] [,z] [,job] [,compz] [,info])
call hseqr(h, w [,ilo] [,ihi] [,z] [,job] [,compz] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes all the eigenvalues, and optionally the Schur factorization, of an upper Hessenberg matrix H : $H = Z^*T^*Z^H$, where T is an upper triangular (or, for real flavors, quasi-triangular) matrix (the Schur form of H), and Z is the unitary or orthogonal matrix whose columns are the Schur vectors z_i .

You can also use this routine to compute the Schur factorization of a general matrix A which has been reduced to upper Hessenberg form H :

$A = Q^*H^*Q^H$, where Q is unitary (orthogonal for real flavors);

$A = (QZ)^*H^*(QZ)^H$.

In this case, after reducing A to Hessenberg form by [?gehrd](#), call [?orghr](#) to form Q explicitly and then pass Q to [?hseqr](#) with `compz = 'V'`.

You can also call `?gebal` to balance the original matrix before reducing it to Hessenberg form by `?hseqr`, so that the Hessenberg matrix H will have the structure:

$$\begin{bmatrix} H_{11} & H_{12} & H_{13} \\ 0 & H_{22} & H_{23} \\ 0 & 0 & H_{33} \end{bmatrix}$$

where H_{11} and H_{33} are upper triangular.

If so, only the central diagonal block H_{22} (in rows and columns ilo to ihi) needs to be further reduced to Schur form (the blocks H_{12} and H_{23} are also affected). Therefore the values of ilo and ihi can be supplied to `?hseqr` directly. Also, after calling this routine you must call `?gebak` to permute the Schur vectors of the balanced matrix to those of the original matrix.

If `?gebal` has not been called, however, then ilo must be set to 1 and ihi to n . Note that if the Schur factorization of A is required, `?gebal` must not be called with $job = 'S'$ or $'B'$, because the balancing transformation is not unitary (for real flavors, it is not orthogonal).

`?hseqr` uses a multishift form of the upper Hessenberg QR algorithm. The Schur vectors are normalized so that $\|z_i\|_2 = 1$, but are determined only to within a complex factor of absolute value 1 (for the real flavors, to within a factor ± 1).

Input Parameters

<i>job</i>	CHARACTER*1. Must be 'E' or 'S'. If <i>job</i> = 'E', then eigenvalues only are required. If <i>job</i> = 'S', then the Schur form T is required.
<i>compz</i>	CHARACTER*1. Must be 'N' or 'I' or 'V'. If <i>compz</i> = 'N', then no Schur vectors are computed (and the array z is not referenced). If <i>compz</i> = 'I', then the Schur vectors of H are computed (and the array z is initialized by the routine). If <i>compz</i> = 'V', then the Schur vectors of A are computed (and the array z must contain the matrix Q on entry).
<i>n</i>	INTEGER. The order of the matrix H ($n \geq 0$).

ilo, ihi INTEGER. If *A* has been balanced by `?gebal`, then *ilo* and *ihi* must contain the values returned by `?gebal`. Otherwise, *ilo* must be set to 1 and *ihi* to *n*.

h, z, work REAL for `shseqr`
DOUBLE PRECISION for `dhseqr`
COMPLEX for `chseqr`
DOUBLE COMPLEX for `zhseqr`.
Arrays:
h(ldh,)* The *n*-by-*n* upper Hessenberg matrix *H*.
The second dimension of *h* must be at least $\max(1, n)$.
z(ldz,)*
If *compz* = 'V', then *z* must contain the matrix *Q* from the reduction to Hessenberg form.
If *compz* = 'I', then *z* need not be set.
If *compz* = 'N', then *z* is not referenced.
The second dimension of *z* must be
at least $\max(1, n)$ if *compz* = 'V' or 'I';
at least 1 if *compz* = 'N'.
work(lwork) is a workspace array.
The dimension of *work* must be at least $\max(1, n)$.

ldh INTEGER. The first dimension of *h*; at least $\max(1, n)$.

ldz INTEGER. The first dimension of *z*;
If *compz* = 'N', then $ldz \geq 1$.
If *compz* = 'V' or 'I', then $ldz \geq \max(1, n)$.

lwork INTEGER. The dimension of the array *work*.
lwork $\geq \max(1, n)$ is sufficient and delivers very good and sometimes optimal performance. However, *lwork* as large as $11*n$ may be required for optimal performance. A workspace query is recommended to determine the optimal workspace size.
If *lwork* = -1, then a workspace query is assumed; the routine only estimates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by `xerbla`. See *Application Notes* for details.

Output Parameters

<i>w</i>	<p>COMPLEX for <i>chseqr</i> DOUBLE COMPLEX for <i>zhseqr</i>. Array, DIMENSION at least $\max(1, n)$. Contains the computed eigenvalues, unless <i>info</i> > 0. The eigenvalues are stored in the same order as on the diagonal of the Schur form <i>T</i> (if computed).</p>
<i>wr, wi</i>	<p>REAL for <i>shseqr</i> DOUBLE PRECISION for <i>dhseqr</i> Arrays, DIMENSION at least $\max(1, n)$ each. Contain the real and imaginary parts, respectively, of the computed eigenvalues, unless <i>info</i> > 0. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having positive imaginary part first. The eigenvalues are stored in the same order as on the diagonal of the Schur form <i>T</i> (if computed).</p>
<i>h</i>	<p>If <i>info</i> = 0 and <i>job</i> = 'S', <i>h</i> contains the upper triangular matrix <i>T</i> from the Schur decomposition (the Schur form). If <i>info</i> = 0 and <i>job</i> = 'E', the contents of <i>h</i> are unspecified on exit. (The output value of <i>h</i> when <i>info</i> > 0 is given under the description of <i>info</i> below.)</p>
<i>z</i>	<p>If <i>compz</i> = 'V' and <i>info</i> = 0, then <i>z</i> contains <i>Q</i>*<i>Z</i>. If <i>compz</i> = 'I' and <i>info</i> = 0, then <i>z</i> contains the unitary or orthogonal matrix <i>Z</i> of the Schur vectors of <i>H</i>. If <i>compz</i> = 'N', then <i>z</i> is not referenced.</p>
<i>work(1)</i>	<p>On exit, if <i>info</i> = 0, then <i>work(1)</i> returns the optimal <i>lwork</i>.</p>
<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value. If <i>info</i> = <i>i</i>, elements 1, 2, ..., <i>ilo</i>-1 and <i>i</i>+1, <i>i</i>+2, ..., <i>n</i> of <i>wr</i> and <i>wi</i> contain the real and imaginary parts of those eigenvalues that have been successively found. If <i>info</i> > 0, and <i>job</i> = 'E', then on exit, the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns <i>ilo</i> through <i>info</i> of the final output value of <i>H</i>.</p>

If $info > 0$, and $job = 'S'$, then on exit (initial value of H)* $U = U$ *(final value of H), where U is a unitary matrix. The final value of H is upper Hessenberg and triangular in rows and columns $info+1$ through ihi .

If $info > 0$, and $compz = 'V'$, then on exit (final value of Z) = (initial value of Z)* U , where U is the unitary matrix (regardless of the value of job).

If $info > 0$, and $compz = 'I'$, then on exit (final value of Z) = U , where U is the unitary matrix (regardless of the value of job).

If $info > 0$, and $compz = 'N'$, then Z is not accessed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hseqr` interface are the following:

<i>h</i>	Holds the matrix H of size (n, n) .
<i>wr</i>	Holds the vector of length n . Used in real flavors only.
<i>wi</i>	Holds the vector of length n . Used in real flavors only.
<i>w</i>	Holds the vector of length n . Used in complex flavors only.
<i>z</i>	Holds the matrix Z of size (n, n) .
<i>job</i>	Must be 'E' or 'S'. The default value is 'E'.
<i>compz</i>	If omitted, this argument is restored based on the presence of argument z as follows: $compz = 'I'$, if z is present, $compz = 'N'$, if z is omitted. If present, $compz$ must be equal to 'I' or 'V' and the argument z must also be present. Note that there will be an error condition if $compz$ is present and z omitted.

Application Notes

The computed Schur factorization is the exact factorization of a nearby matrix $H + E$, where $\|E\|_2 < O(\epsilon)$, $\|H\|_2/s_i$, and ϵ is the machine precision.

If λ_i is an exact eigenvalue, and μ_i is the corresponding computed value, then $|\lambda_i - \mu_i| \leq c(n) * \epsilon * \|H\|_2 / s_i$, where $c(n)$ is a modestly increasing function of n , and s_i is the reciprocal condition number of λ_i . The condition numbers s_i may be computed by calling `?trsna`.

The total number of floating-point operations depends on how rapidly the algorithm converges; typical numbers are as follows.

If only eigenvalues are computed: $7n^3$ for real flavors
 $25n^3$ for complex flavors.

If the Schur form is computed: $10n^3$ for real flavors
 $35n^3$ for complex flavors.

If the full Schur factorization is computed: $20n^3$ for real flavors
 $70n^3$ for complex flavors.

If you are in doubt how much workspace to supply, use a generous value of `lwork` for the first run or set `lwork = -1`.

If you choose the first option and set any of admissible `lwork` sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?hsein

Computes selected eigenvectors of an upper Hessenberg matrix that correspond to specified eigenvalues.

Syntax

FORTRAN 77:

```
call shsein(job, eigsrc, initv, select, n, h, ldh, wr, wi, vl, ldvl, vr, ldvr,
mm, m, work, ifaill, ifailr, info)
```

```
call dhsein(job, eigsrc, initv, select, n, h, ldh, wr, wi, vl, ldvl, vr, ldvr,
mm, m, work, ifaill, ifailr, info)
```

```
call chsein(job, eigsrc, initv, select, n, h, ldh, w, vl, ldvl, vr, ldvr, mm,
m, work, rwork, ifaill, ifailr, info)
```

```
call zhsein(job, eigsrc, initv, select, n, h, ldh, w, vl, ldvl, vr, ldvr, mm,
m, work, rwork, ifaill, ifailr, info)
```

Fortran 95:

```
call hsein(h, wr, wi, select [, vl] [,vr] [,ifaill] [,ifailr] [,initv]
[,eigsrc] [,m] [,info])
```

```
call hsein(h, w, select [,vl] [,vr] [,ifaill] [,ifailr] [,initv] [,eigsrc]
[,m] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes left and/or right eigenvectors of an upper Hessenberg matrix H , corresponding to selected eigenvalues.

The right eigenvector x and the left eigenvector y , corresponding to an eigenvalue λ , are defined by: $H*x = \lambda*x$ and $y^H*H = \lambda*y^H$ (or $H^H*y = \lambda^* *y$). Here λ^* denotes the conjugate of λ .

The eigenvectors are computed by inverse iteration. They are scaled so that, for a real eigenvector x , $\max|x_i| = 1$, and for a complex eigenvector, $\max(|\text{Re}x_i| + |\text{Im}x_i|) = 1$.

If H has been formed by reduction of a general matrix A to upper Hessenberg form, then eigenvectors of H may be transformed to eigenvectors of A by `?ormhr` or `?unmhr`.

Input Parameters

<i>job</i>	<p>CHARACTER*1. Must be 'R' or 'L' or 'B'.</p> <p>If <i>job</i> = 'R', then only right eigenvectors are computed.</p> <p>If <i>job</i> = 'L', then only left eigenvectors are computed.</p> <p>If <i>job</i> = 'B', then all eigenvectors are computed.</p>
<i>eigsrc</i>	<p>CHARACTER*1. Must be 'Q' or 'N'.</p> <p>If <i>eigsrc</i> = 'Q', then the eigenvalues of H were found using ?hseqr; thus if H has any zero sub-diagonal elements (and so is block triangular), then the j-th eigenvalue can be assumed to be an eigenvalue of the block containing the j-th row/column. This property allows the routine to perform inverse iteration on just one diagonal block. If <i>eigsrc</i> = 'N', then no such assumption is made and the routine performs inverse iteration using the whole matrix.</p>
<i>initv</i>	<p>CHARACTER*1. Must be 'N' or 'U'.</p> <p>If <i>initv</i> = 'N', then no initial estimates for the selected eigenvectors are supplied.</p> <p>If <i>initv</i> = 'U', then initial estimates for the selected eigenvectors are supplied in <i>v1</i> and/or <i>vr</i>.</p>
<i>select</i>	<p>LOGICAL.</p> <p>Array, DIMENSION at least $\max(1, n)$. Specifies which eigenvectors are to be computed.</p> <p><i>For real flavors:</i></p> <p>To obtain the real eigenvector corresponding to the real eigenvalue $w_r(j)$, set <i>select(j)</i> to <code>.TRUE.</code></p> <p>To select the complex eigenvector corresponding to the complex eigenvalue ($w_r(j), w_i(j)$) with complex conjugate ($w_r(j+1), w_i(j+1)$), set <i>select(j)</i> and/or <i>select(j+1)</i> to <code>.TRUE.</code>; the eigenvector corresponding to the first eigenvalue in the pair is computed.</p> <p><i>For complex flavors:</i></p> <p>To select the eigenvector corresponding to the eigenvalue $w(j)$, set <i>select(j)</i> to <code>.TRUE.</code></p>
<i>n</i>	<p>INTEGER. The order of the matrix H ($n \geq 0$).</p>
<i>h, v1, vr,</i>	<p>REAL for shsein</p> <p>DOUBLE PRECISION for dhsein</p> <p>COMPLEX for chsein</p>

DOUBLE COMPLEX for zhsein.

Arrays:

$h(ldh,*)$ The n -by- n upper Hessenberg matrix H .
 The second dimension of h must be at least $\max(1, n)$.
 $(ldvl,*)$
 If $initv = 'V'$ and $job = 'L'$ or $'B'$, then vl must contain starting vectors for inverse iteration for the left eigenvectors. Each starting vector must be stored in the same column or columns as will be used to store the corresponding eigenvector.
 If $initv = 'N'$, then vl need not be set.
 The second dimension of vl must be at least $\max(1, mm)$ if $job = 'L'$ or $'B'$ and at least 1 if $job = 'R'$.
 The array vl is not referenced if $job = 'R'$.
 $vr(ldvr,*)$
 If $initv = 'V'$ and $job = 'R'$ or $'B'$, then vr must contain starting vectors for inverse iteration for the right eigenvectors. Each starting vector must be stored in the same column or columns as will be used to store the corresponding eigenvector.
 If $initv = 'N'$, then vr need not be set.
 The second dimension of vr must be at least $\max(1, mm)$ if $job = 'R'$ or $'B'$ and at least 1 if $job = 'L'$.
 The array vr is not referenced if $job = 'L'$.
 $work(*)$ is a workspace array.
 DIMENSION at least $\max(1, n*(n+2))$ for real flavors and at least $\max(1, n*n)$ for complex flavors.

ldh INTEGER. The first dimension of h ; at least $\max(1, n)$.

w COMPLEX for chsein
 DOUBLE COMPLEX for zhsein.
 Array, DIMENSION at least $\max(1, n)$.
 Contains the eigenvalues of the matrix H .
 If $eigsrc = 'Q'$, the array must be exactly as returned by ?hseqr.

wr, wi REAL for shsein
 DOUBLE PRECISION for dhsein
 Arrays, DIMENSION at least $\max(1, n)$ each.

	Contain the real and imaginary parts, respectively, of the eigenvalues of the matrix H . Complex conjugate pairs of values must be stored in consecutive elements of the arrays. If $eigsrc = 'Q'$, the arrays must be exactly as returned by ?hseqr.
<i>ldvl</i>	INTEGER. The first dimension of v_l . If $job = 'L'$ or $'B'$, $ldvl \geq \max(1, n)$. If $job = 'R'$, $ldvl \geq 1$.
<i>ldvr</i>	INTEGER. The first dimension of v_r . If $job = 'R'$ or $'B'$, $ldvr \geq \max(1, n)$. If $job = 'L'$, $ldvr \geq 1$.
<i>mm</i>	INTEGER. The number of columns in v_l and/or v_r . Must be at least m , the actual number of columns required (see <i>Output Parameters</i> below). For real flavors, m is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector (see <i>select</i>). For complex flavors, m is the number of selected eigenvectors (see <i>select</i>). Constraint: $0 \leq mm \leq n$.
<i>rwork</i>	REAL for chsein DOUBLE PRECISION for zhsein. Array, DIMENSION at least $\max(1, n)$.

Output Parameters

<i>select</i>	Overwritten for real flavors only. If a complex eigenvector was selected as specified above, then $select(j)$ is set to <code>.TRUE.</code> and $select(j+1)$ to <code>.FALSE.</code>
<i>w</i>	The real parts of some elements of w may be modified, as close eigenvalues are perturbed slightly in searching for independent eigenvectors.

<i>wr</i>	Some elements of <i>wr</i> may be modified, as close eigenvalues are perturbed slightly in searching for independent eigenvectors.
<i>v1, vr</i>	<p>If <i>job</i> = 'L' or 'B', <i>v1</i> contains the computed left eigenvectors (as specified by <i>select</i>).</p> <p>If <i>job</i> = 'R' or 'B', <i>vr</i> contains the computed right eigenvectors (as specified by <i>select</i>).</p> <p>The eigenvectors are stored consecutively in the columns of the array, in the same order as their eigenvalues.</p> <p><i>For real flavors:</i> a real eigenvector corresponding to a selected real eigenvalue occupies one column; a complex eigenvector corresponding to a selected complex eigenvalue occupies two columns: the first column holds the real part and the second column holds the imaginary part.</p>
<i>m</i>	<p>INTEGER. <i>For real flavors:</i> the number of columns of <i>v1</i> and/or <i>vr</i> required to store the selected eigenvectors.</p> <p><i>For complex flavors:</i> the number of selected eigenvectors.</p>
<i>ifaill, ifailr</i>	<p>INTEGER.</p> <p>Arrays, DIMENSION at least $\max(1, mm)$ each.</p> <p><i>ifaill</i>(<i>i</i>) = 0 if the <i>i</i>th column of <i>v1</i> converged;</p> <p><i>ifaill</i>(<i>i</i>) = <i>j</i> > 0 if the eigenvector stored in the <i>i</i>-th column of <i>v1</i> (corresponding to the <i>j</i>th eigenvalue) failed to converge.</p> <p><i>ifailr</i>(<i>i</i>) = 0 if the <i>i</i>th column of <i>vr</i> converged;</p> <p><i>ifailr</i>(<i>i</i>) = <i>j</i> > 0 if the eigenvector stored in the <i>i</i>-th column of <i>vr</i> (corresponding to the <i>j</i>th eigenvalue) failed to converge.</p> <p><i>For real flavors:</i> if the <i>i</i>th and (<i>i</i>+1)th columns of <i>v1</i> contain a selected complex eigenvector, then <i>ifaill</i>(<i>i</i>) and <i>ifaill</i>(<i>i</i>+1) are set to the same value. A similar rule holds for <i>vr</i> and <i>ifailr</i>.</p> <p>The array <i>ifaill</i> is not referenced if <i>job</i> = 'R'. The array <i>ifailr</i> is not referenced if <i>job</i> = 'L'.</p>
<i>info</i>	<p>INTEGER.</p> <p>If <i>info</i> = 0, the execution is successful.</p> <p>If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

If $info > 0$, then i eigenvectors (as indicated by the parameters $ifaill$ and/or $ifailr$ above) failed to converge. The corresponding columns of $v1$ and/or vr contain no useful information.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hsein` interface are the following:

<code>h</code>	Holds the matrix H of size (n, n) .
<code>wr</code>	Holds the vector of length n . Used in real flavors only.
<code>wi</code>	Holds the vector of length n . Used in real flavors only.
<code>w</code>	Holds the vector of length n . Used in complex flavors only.
<code>select</code>	Holds the vector of length n .
<code>v1</code>	Holds the matrix VL of size (n, mm) .
<code>vr</code>	Holds the matrix VR of size (n, mm) .
<code>ifaill</code>	Holds the vector of length (mm) . Note that there will be an error condition if <code>ifaill</code> is present and <code>v1</code> is omitted.
<code>ifailr</code>	Holds the vector of length (mm) . Note that there will be an error condition if <code>ifailr</code> is present and <code>vr</code> is omitted.
<code>initv</code>	Must be 'N' or 'U'. The default value is 'N'.
<code>eigsrc</code>	Must be 'N' or 'Q'. The default value is 'N'.
<code>job</code>	Restored based on the presence of arguments <code>v1</code> and <code>vr</code> as follows: <code>job</code> = 'B', if both <code>v1</code> and <code>vr</code> are present, <code>job</code> = 'L', if <code>v1</code> is present and <code>vr</code> omitted, <code>job</code> = 'R', if <code>v1</code> is omitted and <code>vr</code> present, Note that there will be an error condition if both <code>v1</code> and <code>vr</code> are omitted.

Application Notes

Each computed right eigenvector x_i is the exact eigenvector of a nearby matrix $A + E_i$, such that $\|E_i\| < O(\epsilon) \|A\|$. Hence the residual is small:

$$\|Ax_i - \lambda_i x_i\| = O(\epsilon) \|A\|.$$

However, eigenvectors corresponding to close or coincident eigenvalues may not accurately span the relevant subspaces.

Similar remarks apply to computed left eigenvectors.

?trevc

Computes selected eigenvectors of an upper (quasi-) triangular matrix computed by ?hseqr.

Syntax

FORTRAN 77:

```
call strevc(side, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, mm, m, work, info)
```

```
call dtrevc(side, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, mm, m, work, info)
```

```
call ctrevc(side, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, mm, m, work, rwork, info)
```

```
call ztrevc(side, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, mm, m, work, rwork, info)
```

Fortran 95:

```
call trevc(t [, howmny] [,select] [,vl] [,vr] [,m] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes some or all of the right and/or left eigenvectors of an upper triangular matrix T (or, for real flavors, an upper quasi-triangular matrix T). Matrices of this type are produced by the Schur factorization of a general matrix: $A = Q^*T^*Q^H$, as computed by [?hseqr](#).

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w , are defined by:

$$T^*x = w^*x, \quad y^H T = w^*y^H, \quad \text{where } y^H \text{ denotes the conjugate transpose of } y.$$

The eigenvalues are not input to this routine, but are read directly from the diagonal blocks of T .

This routine returns the matrices X and/or Y of right and left eigenvectors of T , or the products Q^*X and/or Q^*Y , where Q is an input matrix.

If Q is the orthogonal/unitary factor that reduces a matrix A to Schur form T , then Q^*X and Q^*Y are the matrices of right and left eigenvectors of A .

Input Parameters

side CHARACTER*1. Must be 'R' or 'L' or 'B'.
 If *side* = 'R', then only right eigenvectors are computed.
 If *side* = 'L', then only left eigenvectors are computed.
 If *side* = 'B', then all eigenvectors are computed.

howmny CHARACTER*1. Must be 'A' or 'B' or 'S'.
 If *howmny* = 'A', then all eigenvectors (as specified by *side*) are computed.
 If *howmny* = 'B', then all eigenvectors (as specified by *side*) are computed and backtransformed by the matrices supplied in *vl* and *vr*.
 If *howmny* = 'S', then selected eigenvectors (as specified by *side* and *select*) are computed.

select LOGICAL.
 Array, DIMENSION at least max (1, n).
 If *howmny* = 'S', *select* specifies which eigenvectors are to be computed.
 If *howmny* = 'A' or 'B', *select* is not referenced.
For real flavors:
 If $\omega(j)$ is a real eigenvalue, the corresponding real eigenvector is computed if *select*(j) is .TRUE..
 If $\omega(j)$ and $\omega(j+1)$ are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either *select*(j) or *select*($j+1$) is .TRUE., and on exit *select*(j) is set to .TRUE. and *select*($j+1$) is set to .FALSE..
For complex flavors:
 The eigenvector corresponding to the j -th eigenvalue is computed if *select*(j) is .TRUE..

n INTEGER. The order of the matrix T ($n \geq 0$).

t, vl, vr, REAL for `strevc`
 DOUBLE PRECISION for `dtrevc`

COMPLEX for ctrevc
DOUBLE COMPLEX for ztrevc.

Arrays:

$t(ldt,*)$ contains the n -by- n matrix T in Schur canonical form.
The second dimension of t must be at least $\max(1, n)$.

$vl(ldvl,*)$
If *howmny* = 'B' and *side* = 'L' or 'B', then vl must contain an n -by- n matrix Q (usually the matrix of Schur vectors returned by ?hseqr).
If *howmny* = 'A' or 'S', then vl need not be set.
The second dimension of vl must be at least $\max(1, mm)$ if *side* = 'L' or 'B' and at least 1 if *side* = 'R'.
The array vl is not referenced if *side* = 'R'.

$vr(ldvr,*)$
If *howmny* = 'B' and *side* = 'R' or 'B', then vr must contain an n -by- n matrix Q (usually the matrix of Schur vectors returned by ?hseqr).
If *howmny* = 'A' or 'S', then vr need not be set.
The second dimension of vr must be at least $\max(1, mm)$ if *side* = 'R' or 'B' and at least 1 if *side* = 'L'.
The array vr is not referenced if *side* = 'L'.

$work(*)$ is a workspace array.
DIMENSION at least $\max(1, 3*n)$ for real flavors and at least $\max(1, 2*n)$ for complex flavors.

ldt INTEGER. The first dimension of t ; at least $\max(1, n)$.

ldvl INTEGER. The first dimension of vl .
If *side* = 'L' or 'B', $ldvl \geq n$.
If *side* = 'R', $ldvl \geq 1$.

ldvr INTEGER. The first dimension of vr .
If *side* = 'R' or 'B', $ldvr \geq n$.
If *side* = 'L', $ldvr \geq 1$.

mm INTEGER. The number of columns in the arrays vl and/or vr . Must be at least m (the precise number of columns required).
If *howmny* = 'A' or 'B', $m = n$.

If *howmny* = 'S': for real flavors, *m* is obtained by counting 1 for each selected real eigenvector and 2 for each selected complex eigenvector;
 for complex flavors, *m* is the number of selected eigenvectors (see *select*).

Constraint: $0 \leq m \leq n$.

rwork

REAL for *ctrevc*

DOUBLE PRECISION for *ztrevc*.

Workspace array, DIMENSION at least $\max(1, n)$.

Output Parameters

select

If a complex eigenvector of a real matrix was selected as specified above, then *select*(*j*) is set to .TRUE. and *select*(*j*+1) to .FALSE.

v1, vr

If *side* = 'L' or 'B', *v1* contains the computed left eigenvectors (as specified by *howmny* and *select*).

If *side* = 'R' or 'B', *vr* contains the computed right eigenvectors (as specified by *howmny* and *select*).

The eigenvectors are stored consecutively in the columns of the array, in the same order as their eigenvalues.

For real flavors: corresponding to each real eigenvalue is a real eigenvector, occupying one column; corresponding to each complex conjugate pair of eigenvalues is a complex eigenvector, occupying two columns; the first column holds the real part and the second column holds the imaginary part.

m

INTEGER.

For complex flavors: the number of selected eigenvectors.

If *howmny* = 'A' or 'B', *m* is set to *n*.

For real flavors: the number of columns of *v1* and/or *vr* actually used to store the selected eigenvectors.

If *howmny* = 'A' or 'B', *m* is set to *n*.

info

INTEGER.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trevc` interface are the following:

<code>t</code>	Holds the matrix T of size (n, n) .
<code>select</code>	Holds the vector of length n .
<code>v1</code>	Holds the matrix VL of size (n, mm) .
<code>vr</code>	Holds the matrix VR of size (n, mm) .
<code>side</code>	If omitted, this argument is restored based on the presence of arguments <code>v1</code> and <code>vr</code> as follows: <code>side</code> = 'B', if both <code>v1</code> and <code>vr</code> are present, <code>side</code> = 'L', if <code>vr</code> is omitted, <code>side</code> = 'R', if <code>v1</code> is omitted. Note that there will be an error condition if both <code>v1</code> and <code>vr</code> are omitted.
<code>howmny</code>	If omitted, this argument is restored based on the presence of argument <code>select</code> as follows: <code>howmny</code> = 'V', if <code>q</code> is present, <code>howmny</code> = 'N', if <code>q</code> is omitted. If present, <code>vect</code> = 'V' or 'U' and the argument <code>q</code> must also be present. Note that there will be an error condition if both <code>select</code> and <code>howmny</code> are present.

Application Notes

If x_i is an exact right eigenvector and y_i is the corresponding computed eigenvector, then the angle $\theta(y_i, x_i)$ between them is bounded as follows: $\theta(y_i, x_i) \leq (c(n)\epsilon \|T\|_2) / \text{sep}_i$ where sep_i is the reciprocal condition number of x_i . The condition number sep_i may be computed by calling `?trsna`.

?trsna

Estimates condition numbers for specified eigenvalues and right eigenvectors of an upper (quasi-) triangular matrix.

Syntax

FORTRAN 77:

```
call strсна(job, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, s, sep, mm,
m, work, ldwork, iwork, info)
```

```
call dtrsna(job, howmny, select, n, t, ldt, vl, ldvl, vr, ldvr, s, sep, mm,
m, work, ldwork, iwork, info)
```

m, work, ldwork, rwork, info)
```

Fortran 95:

```
call trсна(t [, s] [,sep] [,vl] [,vr] [,select] [,m] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine estimates condition numbers for specified eigenvalues and/or right eigenvectors of an upper triangular matrix T (or, for real flavors, upper quasi-triangular matrix T in canonical Schur form). These are the same as the condition numbers of the eigenvalues and right eigenvectors of an original matrix $A = Z^*T^*Z^H$ (with unitary or, for real flavors, orthogonal Z), from which T may have been derived.

The routine computes the reciprocal of the condition number of an eigenvalue $\lambda(i)$ as $s_i = |v_H^*u| / (||u||_E ||v||_E)$, where u and v are the right and left eigenvectors of T , respectively, corresponding to $\lambda(i)$. This reciprocal condition number always lies between zero (ill-conditioned) and one (well-conditioned).

An approximate error estimate for a computed eigenvalue $\lambda(i)$ is then given by $\epsilon * ||T|| / s_i$, where ϵ is the *machine precision*.

To estimate the reciprocal of the condition number of the right eigenvector corresponding to $\lambda(i)$, the routine first calls `?trexc` to reorder the eigenvalues so that $\lambda(i)$ is in the leading position:

$$T = Q \begin{bmatrix} \lambda_i & C^H \\ \mathbf{0} & T_{22} \end{bmatrix} Q^H$$

The reciprocal condition number of the eigenvector is then estimated as sep_i , the smallest singular value of the matrix $T_{22} - \lambda(i) * I$. This number ranges from zero (ill-conditioned) to very large (well-conditioned).

An approximate error estimate for a computed right eigenvector u corresponding to $\lambda(i)$ is then given by $\epsilon * \|T\| / sep_i$.

Input Parameters

<i>job</i>	<p>CHARACTER*1. Must be 'E' or 'V' or 'B'.</p> <p>If <i>job</i> = 'E', then condition numbers for eigenvalues only are computed.</p> <p>If <i>job</i> = 'V', then condition numbers for eigenvectors only are computed.</p> <p>If <i>job</i> = 'B', then condition numbers for both eigenvalues and eigenvectors are computed.</p>
<i>howmny</i>	<p>CHARACTER*1. Must be 'A' or 'S'.</p> <p>If <i>howmny</i> = 'A', then the condition numbers for all eigenpairs are computed.</p> <p>If <i>howmny</i> = 'S', then condition numbers for selected eigenpairs (as specified by <i>select</i>) are computed.</p>
<i>select</i>	<p>LOGICAL.</p> <p>Array, DIMENSION at least $\max(1, n)$ if <i>howmny</i> = 'S' and at least 1 otherwise.</p> <p>Specifies the eigenpairs for which condition numbers are to be computed if <i>howmny</i> = 'S'.</p> <p><i>For real flavors:</i></p>

To select condition numbers for the eigenpair corresponding to the real eigenvalue $\lambda(j)$, $select(j)$ must be set

.TRUE.;

to select condition numbers for the eigenpair corresponding to a complex conjugate pair of eigenvalues $\lambda(j)$ and $\lambda(j+1)$, $select(j)$ and/or $select(j+1)$ must be set

.TRUE.

For complex flavors

To select condition numbers for the eigenpair corresponding to the eigenvalue $\lambda(j)$, $select(j)$ must be set .TRUE.

$select$ is not referenced if $howmny = 'A'$.

n

INTEGER. The order of the matrix T ($n \geq 0$).

$t, v1, vr, work$

REAL for $strsna$

DOUBLE PRECISION for $dtrsna$

COMPLEX for $ctrsna$

DOUBLE COMPLEX for $ztrsna$.

Arrays:

$t(ldt,*)$ contains the n -by- n matrix T .

The second dimension of t must be at least $\max(1, n)$.

$v1(ldv1,*)$

If $job = 'E'$ or $'B'$, then $v1$ must contain the left eigenvectors of T (or of any matrix $Q^*T^*Q^H$ with Q unitary or orthogonal) corresponding to the eigenpairs specified by $howmny$ and $select$. The eigenvectors must be stored in consecutive columns of $v1$, as returned by [?trevc](#) or [?hsein](#).

The second dimension of $v1$ must be at least $\max(1, mm)$ if $job = 'E'$ or $'B'$ and at least 1 if $job = 'V'$.

The array $v1$ is not referenced if $job = 'V'$.

$vr(ldvr,*)$

If $job = 'E'$ or $'B'$, then vr must contain the right eigenvectors of T (or of any matrix $Q^*T^*Q^H$ with Q unitary or orthogonal) corresponding to the eigenpairs specified by $howmny$ and $select$. The eigenvectors must be stored in consecutive columns of vr , as returned by [?trevc](#) or [?hsein](#).

The second dimension of vr must be at least $\max(1, mm)$ if $job = 'E'$ or $'B'$ and at least 1 if $job = 'V'$.

	<p>The array <i>vr</i> is not referenced if <i>job</i> = 'V'. <i>work</i> is a workspace array, its dimension (<i>ldwork</i>, <i>n</i>+6). The array <i>work</i> is not referenced if <i>job</i> = 'E'.</p>
<i>ldt</i>	INTEGER. The first dimension of <i>t</i> ; at least $\max(1, n)$.
<i>ldvl</i>	<p>INTEGER. The first dimension of <i>v1</i>. If <i>job</i> = 'E' or 'B', $ldvl \geq \max(1, n)$. If <i>job</i> = 'V', $ldvl \geq 1$.</p>
<i>ldvr</i>	<p>INTEGER. The first dimension of <i>vr</i>. If <i>job</i> = 'E' or 'B', $ldvr \geq \max(1, n)$. If <i>job</i> = 'R', $ldvr \geq 1$.</p>
<i>mm</i>	<p>INTEGER. The number of elements in the arrays <i>s</i> and <i>sep</i>, and the number of columns in <i>v1</i> and <i>vr</i> (if used). Must be at least <i>m</i> (the precise number required). If <i>howmny</i> = 'A', $m = n$; if <i>howmny</i> = 'S', for real flavors <i>m</i> is obtained by counting 1 for each selected real eigenvalue and 2 for each selected complex conjugate pair of eigenvalues. for complex flavors <i>m</i> is the number of selected eigenpairs (see <i>select</i>). Constraint: $0 \leq m \leq n$.</p>
<i>ldwork</i>	<p>INTEGER. The first dimension of <i>work</i>. If <i>job</i> = 'V' or 'B', $ldwork \geq \max(1, n)$. If <i>job</i> = 'E', $ldwork \geq 1$.</p>
<i>rwork</i>	<p>REAL for <i>ctrсна</i>, <i>ztrsna</i>. Array, DIMENSION at least $\max(1, n)$. The array is not referenced if <i>job</i> = 'E'.</p>
<i>iwork</i>	<p>INTEGER for <i>strсна</i>, <i>dtrsna</i>. Array, DIMENSION at least $\max(1, 2*(n - 1))$. The array is not referenced if <i>job</i> = 'E'.</p>

Output Parameters

<i>s</i>	<p>REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors.</p>
----------	--

Array, DIMENSION at least $\max(1, mm)$ if $job = 'E'$ or $'B'$ and at least 1 if $job = 'V'$.

Contains the reciprocal condition numbers of the selected eigenvalues if $job = 'E'$ or $'B'$, stored in consecutive elements of the array. Thus $s(j)$, $sep(j)$ and the j -th columns of $v1$ and vr all correspond to the same eigenpair (but not in general the j th eigenpair unless all eigenpairs have been selected).

For real flavors: for a complex conjugate pair of eigenvalues, two consecutive elements of S are set to the same value. The array s is not referenced if $job = 'V'$.

sep REAL for single-precision flavors
DOUBLE PRECISION for double-precision flavors.

Array, DIMENSION at least $\max(1, mm)$ if $job = 'V'$ or $'B'$ and at least 1 if $job = 'E'$. Contains the estimated reciprocal condition numbers of the selected right eigenvectors if $job = 'V'$ or $'B'$, stored in consecutive elements of the array.

For real flavors: for a complex eigenvector, two consecutive elements of sep are set to the same value; if the eigenvalues cannot be reordered to compute $sep(j)$, then $sep(j)$ is set to zero; this can only occur when the true value would be very small anyway. The array sep is not referenced if $job = 'E'$.

m INTEGER.

For complex flavors: the number of selected eigenpairs. If $howmny = 'A'$, m is set to n .

For real flavors: the number of elements of s and/or sep actually used to store the estimated condition numbers. If $howmny = 'A'$, m is set to n .

info INTEGER.

If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trсна` interface are the following:

<code>t</code>	Holds the matrix T of size (n, n) .
<code>s</code>	Holds the vector of length (mm) .
<code>sep</code>	Holds the vector of length (mm) .
<code>vl</code>	Holds the matrix VL of size (n, mm) .
<code>vr</code>	Holds the matrix VR of size (n, mm) .
<code>select</code>	Holds the vector of length n .
<code>job</code>	Restored based on the presence of arguments <code>s</code> and <code>sep</code> as follows: <code>job</code> = 'B', if both <code>s</code> and <code>sep</code> are present, <code>job</code> = 'E', if <code>s</code> is present and <code>sep</code> omitted, <code>job</code> = 'V', if <code>s</code> is omitted and <code>sep</code> present. Note an error condition if both <code>s</code> and <code>sep</code> are omitted.
<code>howmny</code>	Restored based on the presence of the argument <code>select</code> as follows: <code>howmny</code> = 'S', if <code>select</code> is present, <code>howmny</code> = 'A', if <code>select</code> is omitted.

Note that the arguments `s`, `vl`, and `vr` must either be all present or all omitted.

Otherwise, an error condition is observed.

Application Notes

The computed values `sepi` may overestimate the true value, but seldom by a factor of more than 3.

?trexc

Reorders the Schur factorization of a general matrix.

Syntax

FORTRAN 77:

```
call strexc(compq, n, t, ldt, q, ldq, ifst, ilst, work, info)
```

```
call dtrexc(compq, n, t, ldt, q, ldq, ifst, ilst, work, info)
```

```
call ctrexc(compq, n, t, ldt, q, ldq, ifst, ilst, info)
```

```
call ztrexc(compq, n, t, ldt, q, ldq, ifst, ilst, info)
```

Fortran 95:

```
call trexc(t, ifst, ilst [,q] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reorders the Schur factorization of a general matrix $A = Q^*T^*Q^H$, so that the diagonal element or block of T with row index $ifst$ is moved to row $ilst$.

The reordered Schur form S is computed by an unitary (or, for real flavors, orthogonal) similarity transformation: $S = Z^H*T*Z$. Optionally the updated matrix P of Schur vectors is computed as $P = Q*Z$, giving $A = P*S*P^H$.

Input Parameters

<i>compq</i>	CHARACTER*1. Must be 'V' or 'N'. If <i>compq</i> = 'V', then the Schur vectors (Q) are updated. If <i>compq</i> = 'N', then no Schur vectors are updated.
<i>n</i>	INTEGER. The order of the matrix T ($n \geq 0$).
<i>t</i> , <i>q</i>	REAL for <code>strex</code> DOUBLE PRECISION for <code>dtrex</code> COMPLEX for <code>ctrex</code> DOUBLE COMPLEX for <code>ztrexc</code> . Arrays: <i>t</i> (<i>ldt</i> ,*) contains the n -by- n matrix T . The second dimension of <i>t</i> must be at least $\max(1, n)$. <i>q</i> (<i>ldq</i> ,*) If <i>compq</i> = 'V', then <i>q</i> must contain Q (Schur vectors). If <i>compq</i> = 'N', then <i>q</i> is not referenced. The second dimension of <i>q</i> must be at least $\max(1, n)$ if <i>compq</i> = 'V' and at least 1 if <i>compq</i> = 'N'.
<i>ldt</i>	INTEGER. The first dimension of <i>t</i> ; at least $\max(1, n)$.
<i>ldq</i>	INTEGER. The first dimension of <i>q</i> ; If <i>compq</i> = 'N', then $ldq \geq 1$. If <i>compq</i> = 'V', then $ldq \geq \max(1, n)$.
<i>ifst</i> , <i>ilst</i>	INTEGER. $1 \leq ifst \leq n$; $1 \leq ilst \leq n$.

Must specify the reordering of the diagonal elements (or blocks, which is possible for real flavors) of the matrix T . The element (or block) with row index $ifst$ is moved to row $ilst$ by a sequence of exchanges between adjacent elements (or blocks).

work REAL for `strex`
 DOUBLE PRECISION for `dtrex`.
 Array, DIMENSION at least $\max(1, n)$.

Output Parameters

t Overwritten by the updated matrix s .

q If $compq = 'V'$, q contains the updated matrix of Schur vectors.

ifst, ilst Overwritten for real flavors only.
 If $ifst$ pointed to the second row of a 2 by 2 block on entry, it is changed to point to the first row; $ilst$ always points to the first row of the block in its final position (which may differ from its input value by ± 1).

info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trexc` interface are the following:

t Holds the matrix T of size (n, n) .

q Holds the matrix Q of size (n, n) .

compq Restored based on the presence of the argument q as follows:
 $compq = 'V'$, if q is present,
 $compq = 'N'$, if q is omitted.

Application Notes

The computed matrix S is exactly similar to a matrix $T+E$, where $\|E\|_2 = O(\epsilon) * \|T\|_2$, and ϵ is the machine precision.

Note that if a 2 by 2 diagonal block is involved in the re-ordering, its off-diagonal elements are in general changed; the diagonal elements and the eigenvalues of the block are unchanged unless the block is sufficiently ill-conditioned, in which case they may be noticeably altered. It is possible for a 2 by 2 block to break into two 1 by 1 blocks, that is, for a pair of complex eigenvalues to become purely real.

The values of eigenvalues however are never changed by the re-ordering.

The approximate number of floating-point operations is

for real flavors:	$6n(\text{ifst}-\text{ilst})$ if $\text{compq} = \text{'N'}$;
	$12n(\text{ifst}-\text{ilst})$ if $\text{compq} = \text{'V'}$;
for complex flavors:	$20n(\text{ifst}-\text{ilst})$ if $\text{compq} = \text{'N'}$;
	$40n(\text{ifst}-\text{ilst})$ if $\text{compq} = \text{'V'}$.

?trsens

Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues.

Syntax

FORTRAN 77:

```
call strsen(job, compq, select, n, t, ldt, q, ldq, wr, wi, m, s, sep, work,
lwork, iwork, liwork, info)

call dtrsens(job, compq, select, n, t, ldt, q, ldq, wr, wi, m, s, sep, work,
lwork, iwork, liwork, info)

call ctrsen(job, compq, select, n, t, ldt, q, ldq, w, m, s, sep, work, lwork,
info)

call ztrsens(job, compq, select, n, t, ldt, q, ldq, w, m, s, sep, work, lwork,
info)
```

Fortran 95:

```
call trsen(t, select [,wr] [,wi] [,m] [,s] [,sep] [,q] [,info])
call trsen(t, select [,w] [,m] [,s] [,sep] [,q] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reorders the Schur factorization of a general matrix $A = Q^*T^*Q^H$ so that a selected cluster of eigenvalues appears in the leading diagonal elements (or, for real flavors, diagonal blocks) of the Schur form. The reordered Schur form R is computed by an unitary (orthogonal) similarity transformation: $R = Z^H * T * Z$. Optionally the updated matrix P of Schur vectors is computed as $P = Q * Z$, giving $A = P * R * P^H$.

Let

$$R = \begin{bmatrix} T_{11} & T_{12} \\ \mathbf{0} & T_{13} \end{bmatrix}$$

where the selected eigenvalues are precisely the eigenvalues of the leading m -by- m submatrix T_{11} . Let P be correspondingly partitioned as $(Q_1 \ Q_2)$ where Q_1 consists of the first m columns of Q . Then $A * Q_1 = Q_1 * T_{11}$, and so the m columns of Q_1 form an orthonormal basis for the invariant subspace corresponding to the selected cluster of eigenvalues.

Optionally the routine also computes estimates of the reciprocal condition numbers of the average of the cluster of eigenvalues and of the invariant subspace.

Input Parameters

job CHARACTER*1. Must be 'N' or 'E' or 'V' or 'B'.
 If *job* = 'N', then no condition numbers are required.
 If *job* = 'E', then only the condition number for the cluster of eigenvalues is computed.
 If *job* = 'V', then only the condition number for the invariant subspace is computed.
 If *job* = 'B', then condition numbers for both the cluster and the invariant subspace are computed.

compq CHARACTER*1. Must be 'V' or 'N'.
 If *compq* = 'V', then *Q* of the Schur vectors is updated.
 If *compq* = 'N', then no Schur vectors are updated.

select LOGICAL.
 Array, DIMENSION at least $\max(1, n)$.
 Specifies the eigenvalues in the selected cluster. To select an eigenvalue $\lambda(j)$, *select(j)* must be .TRUE.
 For real flavors: to select a complex conjugate pair of eigenvalues $\lambda(j)$ and $\lambda(j+1)$ (corresponding 2 by 2 diagonal block), *select(j)* and/or *select(j+1)* must be .TRUE.; the complex conjugate $\lambda(j)$ and $\lambda(j+1)$ must be either both included in the cluster or both excluded.

n INTEGER. The order of the matrix T ($n \geq 0$).

t, q, work REAL for strsen
 DOUBLE PRECISION for dtrsen
 COMPLEX for ctrsen
 DOUBLE COMPLEX for ztrsen.
 Arrays:
t (*ldt*,*) The n -by- n T .
 The second dimension of *t* must be at least $\max(1, n)$.
q (*ldq*,*)
 If *compq* = 'V', then *q* must contain *Q* of Schur vectors.
 If *compq* = 'N', then *q* is not referenced.
 The second dimension of *q* must be at least $\max(1, n)$ if *compq* = 'V' and at least 1 if *compq* = 'N'.
work is a workspace array, its dimension $\max(1, lwork)$.

ldt INTEGER. The first dimension of *t*; at least $\max(1, n)$.

ldq INTEGER. The first dimension of *q*;
 If *compq* = 'N', then $ldq \geq 1$.
 If *compq* = 'V', then $ldq \geq \max(1, n)$.

lwork INTEGER. The dimension of the array *work*.
 If *job* = 'V' or 'B', $lwork \geq \max(1, 2*m*(n-m))$.
 If *job* = 'E', then $lwork \geq \max(1, m*(n-m))$.

If $job = 'N'$, then $lwork \geq 1$ for complex flavors and

$lwork \geq \max(1, n)$ for real flavors.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#). See *Application Notes* for details.

$iwork$

INTEGER. $iwork(liwork)$ is a workspace array. The array $iwork$ is not referenced if $job = 'N'$ or $'E'$.

The actual amount of workspace required cannot exceed $n^2/2$ if $job = 'V'$ or $'B'$.

$liwork$

INTEGER.

The dimension of the array $iwork$.

If $job = 'V'$ or $'B'$, $liwork \geq \max(1, 2m(n-m))$.

If $job = 'E'$ or $'E'$, $liwork \geq 1$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

t

Overwritten by the updated matrix R .

q

If $compq = 'V'$, q contains the updated matrix of Schur vectors; the first m columns of the Q form an orthogonal basis for the specified invariant subspace.

w

COMPLEX for `ctrsen`

DOUBLE COMPLEX for `ztrsen`.

Array, DIMENSION at least $\max(1, n)$. The recorded eigenvalues of R . The eigenvalues are stored in the same order as on the diagonal of R .

wr, wi

REAL for `strsen`

DOUBLE PRECISION for `dtrsen`

	<p>Arrays, DIMENSION at least $\max(1, n)$. Contain the real and imaginary parts, respectively, of the reordered eigenvalues of R. The eigenvalues are stored in the same order as on the diagonal of R. Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.</p>
<i>m</i>	<p>INTEGER. <i>For complex flavors:</i> the number of the specified invariant subspaces, which is the same as the number of selected eigenvalues (see <i>select</i>). <i>For real flavors:</i> the dimension of the specified invariant subspace. The value of <i>m</i> is obtained by counting 1 for each selected real eigenvalue and 2 for each selected complex conjugate pair of eigenvalues (see <i>select</i>). Constraint: $0 \leq m \leq n$.</p>
<i>s</i>	<p>REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. If <i>job</i> = 'E' or 'B', <i>s</i> is a lower bound on the reciprocal condition number of the average of the selected cluster of eigenvalues. If $m = 0$ or n, then $s = 1$. <i>For real flavors:</i> if <i>info</i> = 1, then <i>s</i> is set to zero. <i>s</i> is not referenced if <i>job</i> = 'N' or 'V'.</p>
<i>sep</i>	<p>REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. If <i>job</i> = 'V' or 'B', <i>sep</i> is the estimated reciprocal condition number of the specified invariant subspace. If $m = 0$ or n, then $sep = T$. <i>For real flavors:</i> if <i>info</i> = 1, then <i>sep</i> is set to zero. <i>sep</i> is not referenced if <i>job</i> = 'N' or 'E'.</p>
<i>work</i> (1)	<p>On exit, if <i>info</i> = 0, then <i>work</i>(1) returns the optimal size of <i>lwork</i>.</p>
<i>iwork</i> (1)	<p>On exit, if <i>info</i> = 0, then <i>iwork</i>(1) returns the optimal size of <i>liwork</i>.</p>
<i>info</i>	<p>INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = -<i>i</i>, the <i>i</i>-th parameter had an illegal value.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trsen` interface are the following:

<code>t</code>	Holds the matrix T of size (n, n) .
<code>select</code>	Holds the vector of length n .
<code>wr</code>	Holds the vector of length n . Used in real flavors only.
<code>wi</code>	Holds the vector of length n . Used in real flavors only.
<code>w</code>	Holds the vector of length n . Used in complex flavors only.
<code>q</code>	Holds the matrix Q of size (n, n) .
<code>compq</code>	Restored based on the presence of the argument <code>q</code> as follows: <code>compq</code> = 'V', if <code>q</code> is present, <code>compq</code> = 'N', if <code>q</code> is omitted.
<code>job</code>	Restored based on the presence of arguments <code>s</code> and <code>sep</code> as follows: <code>job</code> = 'B', if both <code>s</code> and <code>sep</code> are present, <code>job</code> = 'E', if <code>s</code> is present and <code>sep</code> omitted, <code>job</code> = 'V', if <code>s</code> is omitted and <code>sep</code> present, <code>job</code> = 'N', if both <code>s</code> and <code>sep</code> are omitted.

Application Notes

The computed matrix R is exactly similar to a matrix $T+E$, where $\|E\|_2 = O(\epsilon) * \|T\|_2$, and ϵ is the machine precision. The computed s cannot underestimate the true reciprocal condition number by more than a factor of $(\min(m, n-m))_{1/2}$; `sep` may differ from the true value by $(m*n-m^2)_{1/2}$. The angle between the computed invariant subspace and the true subspace is $O(\epsilon) * \|A\|_2 / \text{sep}$. Note that if a 2-by-2 diagonal block is involved in the re-ordering, its off-diagonal elements are in general changed; the diagonal elements and the eigenvalues of the block are unchanged unless the block is sufficiently ill-conditioned, in which case they may be noticeably altered. It is possible for a 2-by-2 block to break into two 1-by-1 blocks, that is, for a pair of complex eigenvalues to become purely real. The values of eigenvalues however are never changed by the re-ordering.

If it is not clear how much workspace to supply, use a generous value of `lwork` (or `liwork`) for the first run or set `lwork` = -1 (`liwork` = -1).

If $lwork$ (or $liwork$) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$) on exit. Use this value ($work(1)$, $iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$). This operation is called a workspace query.

Note that if $lwork$ ($liwork$) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?trsyl

Solves Sylvester equation for real quasi-triangular or complex triangular matrices.

Syntax

FORTRAN 77:

```
call strsyl(trana, tranb, isgn, m, n, a, lda, b, ldb, c, ldc, scale, info)
call dtrsyl(trana, tranb, isgn, m, n, a, lda, b, ldb, c, ldc, scale, info)
call ctrsyl(trana, tranb, isgn, m, n, a, lda, b, ldb, c, ldc, scale, info)
call ztrsyl(trana, tranb, isgn, m, n, a, lda, b, ldb, c, ldc, scale, info)
```

Fortran 95:

```
call trsyl(a, b, c, scale [, trana] [,tranb] [,isgn] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves the Sylvester matrix equation $\text{op}(A) * X \pm X * \text{op}(B) = \alpha * C$, where $\text{op}(A) = A$ or A^H , and the matrices A and B are upper triangular (or, for real flavors, upper quasi-triangular in canonical Schur form); $\alpha \leq 1$ is a scale factor determined by the routine to avoid overflow in X ; A is m -by- m , B is n -by- n , and C and X are both m -by- n . The matrix X is obtained by a straightforward process of back substitution.

The equation has a unique solution if and only if $\alpha_i \pm \beta_i \neq 0$, where $\{\alpha_i\}$ and $\{\beta_i\}$ are the eigenvalues of A and B , respectively, and the sign (+ or -) is the same as that used in the equation to be solved.

Input Parameters

<i>trana</i>	<p>CHARACTER*1. Must be 'N' or 'T' or 'C'.</p> <p>If <i>trana</i> = 'N', then $\text{op}(A) = A$.</p> <p>If <i>trana</i> = 'T', then $\text{op}(A) = A^T$ (real flavors only).</p> <p>If <i>trana</i> = 'C' then $\text{op}(A) = A^H$.</p>
<i>tranb</i>	<p>CHARACTER*1. Must be 'N' or 'T' or 'C'.</p> <p>If <i>tranb</i> = 'N', then $\text{op}(B) = B$.</p> <p>If <i>tranb</i> = 'T', then $\text{op}(B) = B^T$ (real flavors only).</p> <p>If <i>tranb</i> = 'C', then $\text{op}(B) = B^H$.</p>
<i>isgn</i>	<p>INTEGER. Indicates the form of the Sylvester equation.</p> <p>If <i>isgn</i> = +1, $\text{op}(A)*X + X*\text{op}(B) = \text{alpha}*C$.</p> <p>If <i>isgn</i> = -1, $\text{op}(A)*X - X*\text{op}(B) = \text{alpha}*C$.</p>
<i>m</i>	<p>INTEGER. The order of A, and the number of rows in x and C ($m \geq 0$).</p>
<i>n</i>	<p>INTEGER. The order of B, and the number of columns in x and C ($n \geq 0$).</p>
<i>a, b, c</i>	<p>REAL for <i>strsyl</i></p> <p>DOUBLE PRECISION for <i>dtrsyl</i></p> <p>COMPLEX for <i>ctrsyl</i></p> <p>DOUBLE COMPLEX for <i>ztrsyl</i>.</p> <p>Arrays:</p> <p><i>a(lda,*)</i> contains the matrix A.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, m)$.</p> <p><i>b(l db,*)</i> contains the matrix B.</p> <p>The second dimension of <i>b</i> must be at least $\max(1, n)$.</p> <p><i>c(ldc,*)</i> contains the matrix C.</p> <p>The second dimension of <i>c</i> must be at least $\max(1, n)$.</p>
<i>lda</i>	<p>INTEGER. The first dimension of <i>a</i>; at least $\max(1, m)$.</p>
<i>ldb</i>	<p>INTEGER. The first dimension of <i>b</i>; at least $\max(1, n)$.</p>
<i>ldc</i>	<p>INTEGER. The first dimension of <i>c</i>; at least $\max(1, n)$.</p>

Output Parameters

<i>c</i>	Overwritten by the solution matrix <i>x</i> .
<i>scale</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. The value of the scale factor α .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, <i>A</i> and <i>B</i> have common or close eigenvalues perturbed values were used to solve the equation.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `trsyl` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>m</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>c</i>	Holds the matrix <i>C</i> of size (<i>m</i> , <i>n</i>).
<i>trana</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>tranb</i>	Must be 'N', 'C', or 'T'. The default value is 'N'.
<i>isgn</i>	Must be +1 or -1. The default value is +1.

Application Notes

Let *x* be the exact, *y* the corresponding computed solution, and *R* the residual matrix: $R = C - (AY \pm YB)$. Then the residual is always small:

$$\|R\|_F = O(\epsilon) * (\|A\|_F + \|B\|_F) * \|Y\|_F.$$

However, *y* is not necessarily the exact solution of a slightly perturbed equation; in other words, the solution is not backwards stable.

For the forward error, the following bound holds:

$$\|Y - X\|_F \leq \|R\|_F / \text{sep}(A, B)$$

but this may be a considerable overestimate. See [Golub96] for a definition of $\text{sep}(A, B)$.

The approximate number of floating-point operations for real flavors is $m^*n^*(m + n)$. For complex flavors it is 4 times greater.

Generalized Nonsymmetric Eigenvalue Problems

This section describes LAPACK routines for solving generalized nonsymmetric eigenvalue problems, reordering the generalized Schur factorization of a pair of matrices, as well as performing a number of related computational tasks.

A *generalized nonsymmetric eigenvalue problem* is as follows: given a pair of nonsymmetric (or non-Hermitian) n -by- n matrices A and B , find the *generalized eigenvalues* λ and the corresponding *generalized eigenvectors* x and y that satisfy the equations

$$Ax = \lambda Bx \text{ (right generalized eigenvectors } x)$$

and

$$y^H A = \lambda y^H B \text{ (left generalized eigenvectors } y).$$

Table 4-6 lists LAPACK routines (FORTRAN 77 interface) used to solve the generalized nonsymmetric eigenvalue problems and the generalized Sylvester equation. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-6 Computational Routines for Solving Generalized Nonsymmetric Eigenvalue Problems

Routine name	Operation performed
?gghrd	Reduces a pair of matrices to generalized upper Hessenberg form using orthogonal/unitary transformations.
?ggbal	Balances a pair of general real or complex matrices.
?ggbak	Forms the right or left eigenvectors of a generalized eigenvalue problem.
?hgeqz	Implements the QZ method for finding the generalized eigenvalues of the matrix pair (H,T).
?tgevc	Computes some or all of the right and/or left generalized eigenvectors of a pair of upper triangular matrices
?tgexc	Reorders the generalized Schur decomposition of a pair of matrices (A,B) so that one diagonal block of (A,B) moves to another row index.

Routine name	Operation performed
?tgsen	Reorders the <i>generalized</i> Schur decomposition of a pair of matrices (A,B) so that a selected cluster of eigenvalues appears in the leading diagonal blocks of (A,B).
?tgsyl	Solves the generalized Sylvester equation.
?tgsna	Estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a pair of matrices in generalized real Schur canonical form.

?gghrd

Reduces a pair of matrices to generalized upper Hessenberg form using orthogonal/unitary transformations.

Syntax

FORTRAN 77:

```
call sgghrd(compq, compz, n, ilo, ihi, a, lda, b, ldb, q, ldq, z, ldz, info)
call dgghrd(compq, compz, n, ilo, ihi, a, lda, b, ldb, q, ldq, z, ldz, info)
call cgghrd(compq, compz, n, ilo, ihi, a, lda, b, ldb, q, ldq, z, ldz, info)
call zgghrd(compq, compz, n, ilo, ihi, a, lda, b, ldb, q, ldq, z, ldz, info)
```

Fortran 95:

```
call gghrd(a, b [,ilo] [,ihi] [,q] [,z] [,compq] [,compz] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reduces a pair of real/complex matrices (A,B) to generalized upper Hessenberg form using orthogonal/unitary transformations, where A is a general matrix and B is upper triangular. The form of the generalized eigenvalue problem is $A*x = \lambda*B*x$, and B is typically made upper triangular by computing its QR factorization and moving the orthogonal matrix Q to the left side of the equation.

This routine simultaneously reduces A to a Hessenberg matrix H :

$$Q^H * A * Z = H$$

and transforms B to another upper triangular matrix T :

$$Q^H * B * Z = T$$

in order to reduce the problem to its standard form $H * Y = \lambda * T * Y$, where $Y = Z^H * X$.

The orthogonal/unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q_1 and Z_1 , so that

$$Q_1 * A * Z_1^H = (Q_1 * Q) * H * (Z_1 * Z)^H$$

$$Q_1 * B * Z_1^H = (Q_1 * Q) * T * (Z_1 * Z)^H$$

If Q_1 is the orthogonal/unitary matrix from the QR factorization of B in the original equation $A * X = \lambda * B * X$, then the routine `?ggghrd` reduces the original problem to generalized Hessenberg form.

Input Parameters

<i>compq</i>	CHARACTER*1. Must be 'N', 'I', or 'V'. If <i>compq</i> = 'N', matrix Q is not computed. If <i>compq</i> = 'I', Q is initialized to the unit matrix, and the orthogonal/unitary matrix Q is returned; If <i>compq</i> = 'V', Q must contain an orthogonal/unitary matrix Q_1 on entry, and the product $Q_1 * Q$ is returned.
<i>compz</i>	CHARACTER*1. Must be 'N', 'I', or 'V'. If <i>compz</i> = 'N', matrix Z is not computed. If <i>compz</i> = 'I', Z is initialized to the unit matrix, and the orthogonal/unitary matrix Z is returned; If <i>compz</i> = 'V', Z must contain an orthogonal/unitary matrix Z_1 on entry, and the product $Z_1 * Z$ is returned.
<i>n</i>	INTEGER. The order of the matrices A and B ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. <i>ilo</i> and <i>ihi</i> mark the rows and columns of A which are to be reduced. It is assumed that A is already upper triangular in rows and columns $1:ilo-1$ and $ihi+1:n$.

Values of ilo and ihi are normally set by a previous call to `?ggbal`; otherwise they should be set to 1 and n respectively.

Constraint:

If $n > 0$, then $1 \leq ilo \leq ihi \leq n$;
if $n = 0$, then $ilo = 1$ and $ihi = 0$.

a, b, q, z

REAL for `sgghrd`

DOUBLE PRECISION for `dgghrd`

COMPLEX for `cgghrd`

DOUBLE COMPLEX for `zgghrd`.

Arrays:

$a(lda,*)$ contains the n -by- n general matrix A . The second dimension of a must be at least $\max(1, n)$.

$b(l db,*)$ contains the n -by- n upper triangular matrix B . The second dimension of b must be at least $\max(1, n)$.

$q(ldq,*)$

If `compq` = 'N', then q is not referenced.

If `compq` = 'V', then q must contain the orthogonal/unitary matrix Q_1 , typically from the QR factorization of B .

The second dimension of q must be at least $\max(1, n)$.

$z(ldz,*)$

If `compq` = 'N', then z is not referenced.

If `compq` = 'V', then z must contain the orthogonal/unitary matrix Z_1 .

The second dimension of z must be at least $\max(1, n)$.

lda

INTEGER. The first dimension of a ; at least $\max(1, n)$.

ldb

INTEGER. The first dimension of b ; at least $\max(1, n)$.

ldq

INTEGER. The first dimension of q ;

If `compq` = 'N', then $ldq \geq 1$.

If `compq` = 'I' or 'V', then $ldq \geq \max(1, n)$.

ldz

INTEGER. The first dimension of z ;

If `compq` = 'N', then $ldz \geq 1$.

If `compq` = 'I' or 'V', then $ldz \geq \max(1, n)$.

Output Parameters

<i>a</i>	On exit, the upper triangle and the first subdiagonal of <i>A</i> are overwritten with the upper Hessenberg matrix <i>H</i> , and the rest is set to zero.
<i>b</i>	On exit, overwritten by the upper triangular matrix $T = Q^H * B * Z$. The elements below the diagonal are set to zero.
<i>q</i>	If <i>compq</i> = 'I', then <i>q</i> contains the orthogonal/unitary matrix <i>Q</i> ; If <i>compq</i> = 'V', then <i>q</i> is overwritten by the product $Q_1 * Q$.
<i>z</i>	If <i>compz</i> = 'I', then <i>z</i> contains the orthogonal/unitary matrix <i>Z</i> ; If <i>compz</i> = 'V', then <i>z</i> is overwritten by the product $Z_1 * Z$.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gghrd* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>q</i>	Holds the matrix <i>Q</i> of size (<i>n</i> , <i>n</i>).
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>).
<i>ilo</i>	Default value for this argument is <i>ilo</i> = 1.
<i>ihi</i>	Default value for this argument is <i>ihi</i> = <i>n</i> .
<i>compq</i>	If omitted, this argument is restored based on the presence of argument <i>q</i> as follows: <i>compq</i> = 'I', if <i>q</i> is present, <i>compq</i> = 'N', if <i>q</i> is omitted. If present, <i>compq</i> must be equal to 'I' or 'V' and the argument <i>q</i> must also be present. Note that there will be an error condition if <i>compq</i> is present and <i>q</i> omitted.
<i>compz</i>	If omitted, this argument is restored based on the presence of argument <i>z</i> as follows: <i>compz</i> = 'I', if <i>z</i> is present, <i>compz</i> = 'N', if <i>z</i> is omitted.

If present, *compz* must be equal to 'I' or 'V' and the argument *z* must also be present. Note that there will be an error condition if *compz* is present and *z* omitted.

sggbal

Balances a pair of general real or complex matrices.

Syntax

FORTRAN 77:

```
call sggbal(job, n, a, lda, b, ldb, ilo, ihi, lscale, rscale, work, info)
call dggbal(job, n, a, lda, b, ldb, ilo, ihi, lscale, rscale, work, info)
call cggbal(job, n, a, lda, b, ldb, ilo, ihi, lscale, rscale, work, info)
call zggbal(job, n, a, lda, b, ldb, ilo, ihi, lscale, rscale, work, info)
```

Fortran 95:

```
call ggbal(a, b [,ilo] [,ihi] [,lscale] [,rscale] [,job] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine balances a pair of general real/complex matrices (A, B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to $ilo-1$ and last $ihi+1$ to n elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ilo to ihi to make the rows and columns as close in norm as possible. Both steps are optional. Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $A^*x = \lambda^*B^*x$.

Input Parameters

job CHARACTER*1. Specifies the operations to be performed on A and B . Must be 'N' or 'P' or 'S' or 'B'.
If *job* = 'N', then no operations are done; simply set $ilo = 1$, $ihi = n$, $lscale(i) = 1.0$ and $rscale(i) = 1.0$ for $i = 1, \dots, n$.

If *job* = 'P', then permute only.
 If *job* = 'S', then scale only.
 If *job* = 'B', then both permute and scale.

n INTEGER. The order of the matrices *A* and *B* ($n \geq 0$).

a, b REAL for *sggbal*
 DOUBLE PRECISION for *dggbal*
 COMPLEX for *cggbal*
 DOUBLE COMPLEX for *zggbal*.

Arrays:
a(lda,)* contains the matrix *A*. The second dimension of *a* must be at least $\max(1, n)$.
b(ldb,)* contains the matrix *B*. The second dimension of *b* must be at least $\max(1, n)$.

lda INTEGER. The first dimension of *a*; at least $\max(1, n)$.

ldb INTEGER. The first dimension of *b*; at least $\max(1, n)$.

work REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
 Workspace array, DIMENSION at least $\max(1, 6n)$ when *job* = 'S' or 'B', or at least 1 when *job* = 'N' or 'P'.

Output Parameters

a, b Overwritten by the balanced matrices *A* and *B*, respectively.
 If *job* = 'N', *a* and *b* are not referenced.

ilo, ihi INTEGER. *ilo* and *ihi* are set to integers such that on exit $a(i, j) = 0$ and $b(i, j) = 0$ if $i > j$ and $j = 1, \dots, ilo - 1$ or $i = ihi + 1, \dots, n$.
 If *job* = 'N' or 'S', then *ilo* = 1 and *ihi* = *n*.

lscale, rscale REAL for single precision flavors
 DOUBLE PRECISION for double precision flavors.
Arrays, DIMENSION at least $\max(1, n)$.
lscale contains details of the permutations and scaling factors applied to the left side of *A* and *B*.
 If P_j is the index of the row interchanged with row *j*, and D_j is the scaling factor applied to row *j*, then
 $lscale(j) = P_j$, for $j = 1, \dots, ilo - 1$
 $= D_j$, for $j = ilo, \dots, ihi$

$= P_j$, for $j = ihi+1, \dots, n$.
rscale contains details of the permutations and scaling factors applied to the right side of *A* and *B*.
 If P_j is the index of the column interchanged with column j , and D_j is the scaling factor applied to column j , then
 $rscale(j) = P_j$, for $j = 1, \dots, ilo-1$
 $= D_j$, for $j = ilo, \dots, ihi$
 $= P_j$, for $j = ihi+1, \dots, n$
 The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggbal` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (n, n) .
<i>lscale</i>	Holds the vector of length (n) .
<i>rscale</i>	Holds the vector of length (n) .
<i>ilo</i>	Default value for this argument is $ilo = 1$.
<i>ihi</i>	Default value for this argument is $ihi = n$.
<i>job</i>	Must be 'B', 'S', 'P', or 'N'. The default value is 'B'.

?ggbak

Forms the right or left eigenvectors of a generalized eigenvalue problem.

Syntax

FORTRAN 77:

```
call sggbak(job, side, n, ilo, ihi, lscale, rscale, m, v, ldv, info)
```

```
call dggbak(job, side, n, ilo, ihi, lscale, rscale, m, v, ldv, info)
call cggbak(job, side, n, ilo, ihi, lscale, rscale, m, v, ldv, info)
call zggbak(job, side, n, ilo, ihi, lscale, rscale, m, v, ldv, info)
```

Fortran 95:

```
call ggbak(v [, ilo] [, ihi] [, lscale] [, rscale] [, job] [, info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine forms the right or left eigenvectors of a real/complex generalized eigenvalue problem

$$A*x = \lambda*B*x$$

by backward transformation on the computed eigenvectors of the balanced pair of matrices output by [?ggbal](#).

Input Parameters

<i>job</i>	CHARACTER*1. Specifies the type of backward transformation required. Must be 'N', 'P', 'S', or 'B'. If <i>job</i> = 'N', then no operations are done; return. If <i>job</i> = 'P', then do backward transformation for permutation only. If <i>job</i> = 'S', then do backward transformation for scaling only. If <i>job</i> = 'B', then do backward transformation for both permutation and scaling. This argument must be the same as the argument <i>job</i> supplied to ?ggbal .
<i>side</i>	CHARACTER*1. Must be 'L' or 'R'. If <i>side</i> = 'L', then <i>v</i> contains left eigenvectors. If <i>side</i> = 'R', then <i>v</i> contains right eigenvectors.
<i>n</i>	INTEGER. The number of rows of the matrix <i>v</i> ($n \geq 0$).
<i>ilo, ihi</i>	INTEGER. The integers <i>ilo</i> and <i>ihi</i> determined by ?ggbal . Constraint: If $n > 0$, then $1 \leq ilo \leq ihi \leq n$; if $n = 0$, then $ilo = 1$ and $ihi = 0$.
<i>lscale, rscale</i>	REAL for single precision flavors

DOUBLE PRECISION for double precision flavors.
 Arrays, DIMENSION at least $\max(1, n)$.
 The array *lscale* contains details of the permutations and/or scaling factors applied to the left side of *A* and *B*, as returned by ?ggbal.
 The array *rscale* contains details of the permutations and/or scaling factors applied to the right side of *A* and *B*, as returned by ?ggbal.

m INTEGER. The number of columns of the matrix *v* ($m \geq 0$).

v REAL for sggbak
 DOUBLE PRECISION for dggbak
 COMPLEX for cggbak
 DOUBLE COMPLEX for zggbak.
 Array $v(ldv,*)$. Contains the matrix of right or left eigenvectors to be transformed, as returned by ?tgevc.
 The second dimension of *v* must be at least $\max(1, m)$.

ldv INTEGER. The first dimension of *v*; at least $\max(1, n)$.

Output Parameters

v Overwritten by the transformed eigenvectors

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *ggbak* interface are the following:

v Holds the matrix *v* of size (n, m) .

lscale Holds the vector of length *n*.

rscale Holds the vector of length *n*.

ilo Default value for this argument is *ilo* = 1.

ihi Default value for this argument is *ihi* = *n*.

<i>job</i>	Must be 'B', 'S', 'P', or 'N'. The default value is 'B'.
<i>side</i>	If omitted, this argument is restored based on the presence of arguments <i>lscale</i> and <i>rscale</i> as follows: <i>side</i> = 'L', if <i>lscale</i> is present and <i>rscale</i> omitted, <i>side</i> = 'R', if <i>lscale</i> is omitted and <i>rscale</i> present. Note that there will be an error condition if both <i>lscale</i> and <i>rscale</i> are present or if they both are omitted.

?hgeqz

Implements the QZ method for finding the generalized eigenvalues of the matrix pair (H,T).

Syntax

FORTRAN 77:

```
call shgeqz(job, compq, compz, n, ilo, ihi, h, ldh, t, ldt, alphas, alphas,
beta, q, ldq, z, ldz, work, lwork, info)
```

```
call dhgeqz(job, compq, compz, n, ilo, ihi, h, ldh, t, ldt, alphas, alphas,
beta, q, ldq, z, ldz, work, lwork, info)
```

```
call chgeqz(job, compq, compz, n, ilo, ihi, h, ldh, t, ldt, alpha, beta, q,
ldq, z, ldz, work, lwork, rwork, info)
```

```
call zhgeqz(job, compq, compz, n, ilo, ihi, h, ldh, t, ldt, alpha, beta, q,
ldq, z, ldz, work, lwork, rwork, info)
```

Fortran 95:

```
call hgeqz(h, t [,ilo] [,ihi] [,alphas] [,alphas] [,beta] [,q] [,z] [,job]
[,compq] [,compz] [,info])
```

```
call hgeqz(h, t [,ilo] [,ihi] [,alpha] [,beta] [,q] [,z] [,job] [,compq] [,
compz] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the eigenvalues of a real/complex matrix pair (H,T) , where H is an upper Hessenberg matrix and T is upper triangular, using the double-shift version (for real flavors) or single-shift version (for complex flavors) of the QZ method. Matrix pairs of this type are produced by the reduction to generalized upper Hessenberg form of a real/complex matrix pair (A,B) :

$$A = Q_1 * H * Z_1^H, B = Q_1 * T * Z_1^H,$$

as computed by `?gghrd`.

For real flavors:

If `job = 'S'`, then the Hessenberg-triangular pair (H,T) is also reduced to generalized Schur form,

$$H = Q * S * Z^T, T = Q * P * Z^T,$$

where Q and Z are orthogonal matrices, P is an upper triangular matrix, and S is a quasi-triangular matrix with 1-by-1 and 2-by-2 diagonal blocks. The 1-by-1 blocks correspond to real eigenvalues of the matrix pair (H,T) and the 2-by-2 blocks correspond to complex conjugate pairs of eigenvalues.

Additionally, the 2-by-2 upper triangular diagonal blocks of P corresponding to 2-by-2 blocks of S are reduced to positive diagonal form, that is, if $S(j+1,j)$ is non-zero, then $P(j+1,j) = P(j,j+1) = 0$, $P(j,j) > 0$, and $P(j+1,j+1) > 0$.

For complex flavors:

If `job = 'S'`, then the Hessenberg-triangular pair (H,T) is also reduced to generalized Schur form,

$$H = Q * S * Z^H, T = Q * P * Z^H,$$

where Q and Z are unitary matrices, and S and P are upper triangular.

For all function flavors:

Optionally, the orthogonal/unitary matrix Q from the generalized Schur factorization may be postmultiplied into an input matrix Q_1 , and the orthogonal/unitary matrix Z may be postmultiplied into an input matrix Z_1 .

If Q_1 and Z_1 are the orthogonal/unitary matrices from `?gghrd` that reduced the matrix pair (A,B) to generalized upper Hessenberg form, then the output matrices $Q_1 Q$ and $Z_1 Z$ are the orthogonal/unitary factors from the generalized Schur factorization of (A,B) :

$$A = (Q_1 Q) * S * (Z_1 Z)^H, B = (Q_1 Q) * P * (Z_1 Z)^H.$$

To avoid overflow, eigenvalues of the matrix pair (H,T) (equivalently, of (A,B)) are computed as a pair of values (α, β) . For `chgeqz/zhgeqz`, α and β are complex, and for `shgeqz/dhgeqz`, α is complex and β real. If β is nonzero, $\lambda = \alpha/\beta$ is an eigenvalue of the generalized nonsymmetric eigenvalue problem (GNEP)

$$A*x = \lambda*B*x$$

and if α is nonzero, $\mu = \beta/\alpha$ is an eigenvalue of the alternate form of the GNEP

$$\mu*A*y = B*y.$$

Real eigenvalues (for real flavors) or the values of α and β for the i -th eigenvalue (for complex flavors) can be read directly from the generalized Schur form:

$$\alpha = S(i,i), \beta = P(i,i).$$

Input Parameters

<i>job</i>	CHARACTER*1. Specifies the operations to be performed. Must be 'E' or 'S'. If <i>job</i> = 'E', then compute eigenvalues only; If <i>job</i> = 'S', then compute eigenvalues and the Schur form.
<i>compq</i>	CHARACTER*1. Must be 'N', 'I', or 'V'. If <i>compq</i> = 'N', left Schur vectors (q) are not computed; If <i>compq</i> = 'I', q is initialized to the unit matrix and the matrix of left Schur vectors of (H,T) is returned; If <i>compq</i> = 'V', q must contain an orthogonal/unitary matrix Q_1 on entry and the product Q_1*Q is returned.
<i>compz</i>	CHARACTER*1. Must be 'N', 'I', or 'V'. If <i>compz</i> = 'N', right Schur vectors (z) are not computed; If <i>compz</i> = 'I', z is initialized to the unit matrix and the matrix of right Schur vectors of (H,T) is returned; If <i>compz</i> = 'V', z must contain an orthogonal/unitary matrix Z_1 on entry and the product Z_1*Z is returned.
<i>n</i>	INTEGER. The order of the matrices H , T , Q , and Z ($n \geq 0$).

ilo, ihi INTEGER. *ilo* and *ihi* mark the rows and columns of H which are in Hessenberg form. It is assumed that H is already upper triangular in rows and columns $1:iho-1$ and $ihi+1:n$.

Constraint:
 If $n > 0$, then $1 \leq ilo \leq ihi \leq n$;
 if $n = 0$, then $ilo = 1$ and $ihi = 0$.

h, t, q, z, work REAL for shgeqz
 DOUBLE PRECISION for dhgeqz
 COMPLEX for chgeqz
 DOUBLE COMPLEX for zhgeqz.

Arrays:
 On entry, $h(ldh,*)$ contains the n -by- n upper Hessenberg matrix H .
 The second dimension of h must be at least $\max(1, n)$.
 On entry, $t(ldt,*)$ contains the n -by- n upper triangular matrix T .
 The second dimension of t must be at least $\max(1, n)$.
 $q(ldq,*)$:
 On entry, if $compq = 'V'$, this array contains the orthogonal/unitary matrix Q_1 used in the reduction of (A,B) to generalized Hessenberg form.
 If $compq = 'N'$, then q is not referenced.
 The second dimension of q must be at least $\max(1, n)$.
 $z(ldz,*)$:
 On entry, if $compz = 'V'$, this array contains the orthogonal/unitary matrix Z_1 used in the reduction of (A,B) to generalized Hessenberg form.
 If $compz = 'N'$, then z is not referenced.
 The second dimension of z must be at least $\max(1, n)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.

ldh INTEGER. The first dimension of h ; at least $\max(1, n)$.

ldt INTEGER. The first dimension of t ; at least $\max(1, n)$.

ldq INTEGER. The first dimension of q ;
 If $compq = 'N'$, then $ldq \geq 1$.
 If $compq = 'I'$ or $'V'$, then $ldq \geq \max(1, n)$.

<i>ldz</i>	<p>INTEGER. The first dimension of <i>z</i>;</p> <p>If <i>compq</i> = 'N', then $ldz \geq 1$.</p> <p>If <i>compq</i> = 'I' or 'V', then $ldz \geq \max(1, n)$.</p>
<i>lwork</i>	<p>INTEGER. The dimension of the array <i>work</i>.</p> <p>$lwork \geq \max(1, n)$.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla. See <i>Application Notes</i> for details.</p>
<i>rwork</i>	<p>REAL for <i>chgeqz</i></p> <p>DOUBLE PRECISION for <i>zhgeqz</i>.</p> <p>Workspace array, DIMENSION at least $\max(1, n)$. Used in complex flavors only.</p>

Output Parameters

<i>h</i>	<p><i>For real flavors:</i></p> <p>If <i>job</i> = 'S', then, on exit, <i>h</i> contains the upper quasi-triangular matrix <i>s</i> from the generalized Schur factorization; 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $h(i, i) = h(i+1, i+1)$ and $h(i+1, i) * h(i, i+1) < 0$.</p> <p>If <i>job</i> = 'E', then on exit the diagonal blocks of <i>h</i> match those of <i>s</i>, but the rest of <i>h</i> is unspecified.</p> <p><i>For complex flavors:</i></p> <p>If <i>job</i> = 'S', then, on exit, <i>h</i> contains the upper triangular matrix <i>s</i> from the generalized Schur factorization.</p> <p>If <i>job</i> = 'E', then on exit the diagonal of <i>h</i> matches that of <i>s</i>, but the rest of <i>h</i> is unspecified.</p>
<i>t</i>	<p>If <i>job</i> = 'S', then, on exit, <i>t</i> contains the upper triangular matrix <i>p</i> from the generalized Schur factorization.</p> <p><i>For real flavors:</i></p>

2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks of S are reduced to positive diagonal form, that is, if $h(j+1,j)$ is non-zero, then $t(j+1,j)=t(j,j+1)=0$ and $t(j,j)$ and $t(j+1,j+1)$ will be positive.

If $job = 'E'$, then on exit the diagonal blocks of t match those of P , but the rest of t is unspecified.

For complex flavors:
if $job = 'E'$, then on exit the diagonal of t matches that of P , but the rest of t is unspecified.

alphar, alphai REAL for shgeqz;
DOUBLE PRECISION for dhgeqz.
Arrays, DIMENSION at least $\max(1, n)$. The real and imaginary parts, respectively, of each scalar $alpha$ defining an eigenvalue of GNEP.
If $alphai(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -th eigenvalues are a complex conjugate pair, with $alphai(j+1) = -alphai(j)$.

alpha COMPLEX for chgeqz;
DOUBLE COMPLEX for zhgeqz.
Array, DIMENSION at least $\max(1, n)$.
The complex scalars $alpha$ that define the eigenvalues of GNEP. $alphai(i) = S(i,i)$ in the generalized Schur factorization.

beta REAL for shgeqz
DOUBLE PRECISION for dhgeqz
COMPLEX for chgeqz
DOUBLE COMPLEX for zhgeqz.
Array, DIMENSION at least $\max(1, n)$.
For real flavors:
The scalars $beta$ that define the eigenvalues of GNEP. Together, the quantities $alpha = (alphar(j), alphai(j))$ and $beta = beta(j)$ represent the j -th eigenvalue of the matrix pair (A,B) , in one of the forms $lambda = alpha/beta$ or $mu = beta/alpha$. Since either $lambda$ or mu may overflow, they should not, in general, be computed.
For complex flavors:

	<p>The real non-negative scalars β that define the eigenvalues of GNEP.</p> <p>$\beta(i) = P(i, i)$ in the generalized Schur factorization. Together, the quantities $\alpha = \alpha(j)$ and $\beta = \beta(j)$ represent the j-th eigenvalue of the matrix pair (A, B), in one of the forms $\lambda = \alpha/\beta$ or $\mu = \beta/\alpha$. Since either λ or μ may overflow, they should not, in general, be computed.</p>
q	<p>On exit, if $compq = 'I'$, q is overwritten by the orthogonal/unitary matrix of left Schur vectors of the pair (H, T), and if $compq = 'V'$, q is overwritten by the orthogonal/unitary matrix of left Schur vectors of (A, B).</p>
z	<p>On exit, if $compz = 'I'$, z is overwritten by the orthogonal/unitary matrix of right Schur vectors of the pair (H, T), and if $compz = 'V'$, z is overwritten by the orthogonal/unitary matrix of right Schur vectors of (A, B).</p>
$work(1)$	<p>If $info \geq 0$, on exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.</p>
$info$	<p>INTEGER.</p> <p>If $info = 0$, the execution is successful.</p> <p>If $info = -i$, the i-th parameter had an illegal value.</p> <p>If $info = 1, \dots, n$, the QZ iteration did not converge. (H, T) is not in Schur form, but $\alpha_{\text{har}}(i)$, $\alpha_{\text{hai}}(i)$ (for real flavors), $\alpha(i)$ (for complex flavors), and $\beta(i)$, $i = info + 1, \dots, n$ should be correct.</p> <p>If $info = n + 1, \dots, 2n$, the shift calculation failed. (H, T) is not in Schur form, but $\alpha_{\text{har}}(i)$, $\alpha_{\text{hai}}(i)$ (for real flavors), $\alpha(i)$ (for complex flavors), and $\beta(i)$, $i = info - n + 1, \dots, n$ should be correct.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hgeqz` interface are the following:

<i>h</i>	Holds the matrix H of size (n, n) .
<i>t</i>	Holds the matrix T of size (n, n) .
<i>alphar</i>	Holds the vector of length n . Used in real flavors only.
<i>alpha</i>	Holds the vector of length n . Used in real flavors only.
<i>alpha</i>	Holds the vector of length n . Used in complex flavors only.
<i>beta</i>	Holds the vector of length n .
<i>q</i>	Holds the matrix Q of size (n, n) .
<i>z</i>	Holds the matrix Z of size (n, n) .
<i>ilo</i>	Default value for this argument is $ilo = 1$.
<i>ihi</i>	Default value for this argument is $ihi = n$.
<i>job</i>	Must be 'E' or 'S'. The default value is 'E'.
<i>compq</i>	If omitted, this argument is restored based on the presence of argument q as follows: <i>compq</i> = 'I', if q is present, <i>compq</i> = 'N', if q is omitted. If present, <i>compq</i> must be equal to 'I' or 'V' and the argument q must also be present. Note that there will be an error condition if <i>compq</i> is present and q omitted.
<i>compz</i>	If omitted, this argument is restored based on the presence of argument z as follows: <i>compz</i> = 'I', if z is present, <i>compz</i> = 'N', if z is omitted. If present, <i>compz</i> must be equal to 'I' or 'V' and the argument z must also be present. Note an error condition if <i>compz</i> is present and z is omitted.

Application Notes

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tgevc

Computes some or all of the right and/or left generalized eigenvectors of a pair of upper triangular matrices.

Syntax

FORTRAN 77:

```
call stgevc(side, howmny, select, n, s, lds, p, ldp, vl, ldvl, vr, ldvr, mm,
m, work, info)
```

```
call dtgevc(side, howmny, select, n, s, lds, p, ldp, vl, ldvl, vr, ldvr, mm,
m, work, info)
```

```
call ctgevc(side, howmny, select, n, s, lds, p, ldp, vl, ldvl, vr, ldvr, mm,
m, work, rwork, info)
```

```
call ztgevc(side, howmny, select, n, s, lds, p, ldp, vl, ldvl, vr, ldvr, mm,
m, work, rwork, info)
```

Fortran 95:

```
call tgevc(s, p [,howmny] [,select] [,vl] [,vr] [,m] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes some or all of the right and/or left eigenvectors of a pair of real/complex matrices (S,P) , where S is quasi-triangular (for real flavors) or upper triangular (for complex flavors) and P is upper triangular.

Matrix pairs of this type are produced by the generalized Schur factorization of a real/complex matrix pair (A,B) :

$$A = Q^*S^*Z^H, B = Q^*P^*Z^H$$

as computed by ?gghrd plus ?hgeqz.

The right eigenvector x and the left eigenvector y of (S,P) corresponding to an eigenvalue w are defined by:

$$S^*x = w^*P^*x, y^H*S = w^*y^H*P$$

The eigenvalues are not input to this routine, but are computed directly from the diagonal blocks or diagonal elements of S and P .

This routine returns the matrices X and/or Y of right and left eigenvectors of (S,P) , or the products Z^*X and/or Q^*Y , where Z and Q are input matrices.

If Q and Z are the orthogonal/unitary factors from the generalized Schur factorization of a matrix pair (A,B) , then Z^*X and Q^*Y are the matrices of right and left eigenvectors of (A,B) .

Input Parameters

side CHARACTER*1. Must be 'R', 'L', or 'B'.
 If *side* = 'R', compute right eigenvectors only.
 If *side* = 'L', compute left eigenvectors only.
 If *side* = 'B', compute both right and left eigenvectors.

howmny CHARACTER*1. Must be 'A', 'B', or 'S'.
 If *howmny* = 'A', compute all right and/or left eigenvectors.
 If *howmny* = 'B', compute all right and/or left eigenvectors, backtransformed by the matrices in *vr* and/or *vl*.
 If *howmny* = 'S', compute selected right and/or left eigenvectors, specified by the logical array *select*.

select LOGICAL.
 Array, DIMENSION at least max(1, n).
 If *howmny* = 'S', *select* specifies the eigenvectors to be computed.
 If *howmny* = 'A' or 'B', *select* is not referenced.
 For real flavors:
 If *omega(j)* is a real eigenvalue, the corresponding real eigenvector is computed if *select(j)* is .TRUE..

If $\omega(j)$ and $\omega(j+1)$ are the real and imaginary parts of a complex eigenvalue, the corresponding complex eigenvector is computed if either $select(j)$ or $select(j+1)$ is `.TRUE.`, and on exit $select(j)$ is set to `.TRUE.` and $select(j+1)$ is set to `.FALSE.`.

For complex flavors:

The eigenvector corresponding to the j -th eigenvalue is computed if $select(j)$ is `.TRUE.`.

n

INTEGER. The order of the matrices S and P ($n \geq 0$).

$s, p, vl, vr, work$

REAL for `stgevc`

DOUBLE PRECISION for `dtgevc`

COMPLEX for `ctgevc`

DOUBLE COMPLEX for `ztgevc`.

Arrays:

$s(lds,*)$ contains the matrix S from a generalized Schur factorization as computed by `?hgeqz`. This matrix is upper quasi-triangular for real flavors, and upper triangular for complex flavors.

The second dimension of s must be at least $\max(1, n)$.

$p(ldp,*)$ contains the upper triangular matrix P from a generalized Schur factorization as computed by `?hgeqz`.

For real flavors, 2-by-2 diagonal blocks of P corresponding to 2-by-2 blocks of S must be in positive diagonal form.

For complex flavors, P must have real diagonal elements.

The second dimension of p must be at least $\max(1, n)$.

If $side = 'L'$ or $'B'$ and $howmny = 'B'$, $vl(ldvl,*)$ must contain an n -by- n matrix Q (usually the orthogonal/unitary matrix Q of left Schur vectors returned by `?hgeqz`).

The second dimension of vl must be at least $\max(1, mm)$.

If $side = 'R'$, vl is not referenced.

If $side = 'R'$ or $'B'$ and $howmny = 'B'$, $vr(ldvr,*)$ must contain an n -by- n matrix Z (usually the orthogonal/unitary matrix Z of right Schur vectors returned by `?hgeqz`).

The second dimension of vr must be at least $\max(1, mm)$.

If $side = 'L'$, vr is not referenced.

$work(*)$ is a workspace array.

DIMENSION at least $\max(1, 6*n)$ for real flavors and at least $\max(1, 2*n)$ for complex flavors.

<i>lds</i>	INTEGER. The first dimension of <i>s</i> ; at least $\max(1, n)$.
<i>ldp</i>	INTEGER. The first dimension of <i>p</i> ; at least $\max(1, n)$.
<i>ldvl</i>	INTEGER. The first dimension of <i>vl</i> ; If <i>side</i> = 'L' or 'B', then $ldvl \geq n$. If <i>side</i> = 'R', then $ldvl \geq 1$.
<i>ldvr</i>	INTEGER. The first dimension of <i>vr</i> ; If <i>side</i> = 'R' or 'B', then $ldvr \geq n$. If <i>side</i> = 'L', then $ldvr \geq 1$.
<i>mm</i>	INTEGER. The number of columns in the arrays <i>vl</i> and/or <i>vr</i> ($mm \geq m$).
<i>rwork</i>	REAL for ctgevc DOUBLE PRECISION for ztgevc. Workspace array, DIMENSION at least $\max(1, 2*n)$. Used in complex flavors only.

Output Parameters

<i>vl</i>	On exit, if <i>side</i> = 'L' or 'B', <i>vl</i> contains: if <i>howmny</i> = 'A', the matrix <i>Y</i> of left eigenvectors of (<i>S</i> , <i>P</i>); if <i>howmny</i> = 'B', the matrix <i>Q</i> * <i>Y</i> ; if <i>howmny</i> = 'S', the left eigenvectors of (<i>S</i> , <i>P</i>) specified by <i>select</i> , stored consecutively in the columns of <i>vl</i> , in the same order as their eigenvalues. <i>For real flavors:</i> A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.
<i>vr</i>	On exit, if <i>side</i> = 'R' or 'B', <i>vr</i> contains: if <i>howmny</i> = 'A', the matrix <i>X</i> of right eigenvectors of (<i>S</i> , <i>P</i>); if <i>howmny</i> = 'B', the matrix <i>Z</i> * <i>X</i> ; if <i>howmny</i> = 'S', the right eigenvectors of (<i>S</i> , <i>P</i>) specified by <i>select</i> , stored consecutively in the columns of <i>vr</i> , in the same order as their eigenvalues. <i>For real flavors:</i> A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

m INTEGER. The number of columns in the arrays *v1* and/or *vr* actually used to store the eigenvectors.
 If *howmny* = 'A' or 'B', *m* is set to *n*.
 For real flavors:
 Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.
 For complex flavors:
 Each selected eigenvector occupies one column.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 For real flavors:
 if *info* = *i*>0, the 2-by-2 block (*i*:*i*+1) does not have a complex eigenvalue.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgevc` interface are the following:

s Holds the matrix *S* of size (*n*,*n*).

p Holds the matrix *P* of size (*n*,*n*).

select Holds the vector of length *n*.

v1 Holds the matrix *VL* of size (*n*,*mm*).

vr Holds the matrix *VR* of size (*n*,*mm*).

side Restored based on the presence of arguments *v1* and *vr* as follows:
side = 'B', if both *v1* and *vr* are present,
side = 'L', if *v1* is present and *vr* omitted,
side = 'R', if *v1* is omitted and *vr* present,
 Note that there will be an error condition if both *v1* and *vr* are omitted.

howmny If omitted, this argument is restored based on the presence of argument *select* as follows:
howmny = 'S', if *select* is present,
howmny = 'A', if *select* is omitted.
 If present, *howmny* must be equal to 'A' or 'B' and the argument *select* must be omitted.

Note that there will be an error condition if both *howmny* and *select* are present.

?tgexc

Reorders the generalized Schur decomposition of a pair of matrices (A,B) so that one diagonal block of (A,B) moves to another row index.

Syntax

FORTRAN 77:

```
call stgexc(wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, ifst, ilst, work,
           lwork, info)
```

```
call dtgexc(wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, ifst, ilst, work,
           lwork, info)
```

```
call ctgexc(wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, ifst, ilst, info)
```

```
call ztgexc(wantq, wantz, n, a, lda, b, ldb, q, ldq, z, ldz, ifst, ilst, info)
```

Fortran 95:

```
call tgexc(a, b [,ifst] [,ilst] [,z] [,q] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reorders the generalized real-Schur/Schur decomposition of a real/complex matrix pair (A,B) using an orthogonal/unitary equivalence transformation

$$(A,B) = Q*(A,B)*Z^H,$$

so that the diagonal block of (A,B) with row index *ifst* is moved to row *ilst*. Matrix pair (A,B) must be in a generalized real-Schur/Schur canonical form (as returned by `?gges`), that is, A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks and B is upper triangular. Optionally, the matrices Q and Z of generalized Schur vectors are updated.

$$Q(\text{in}) * A(\text{in}) * Z(\text{in})' = Q(\text{out}) * A(\text{out}) * Z(\text{out})'$$

$$Q(\text{in}) * B(\text{in}) * Z(\text{in})' = Q(\text{out}) * B(\text{out}) * Z(\text{out})'.$$

Input Parameters

<i>wantq, wantz</i>	<p>LOGICAL.</p> <p>If <i>wantq</i> = <code>.TRUE.</code>, update the left transformation matrix <i>Q</i>;</p> <p>If <i>wantq</i> = <code>.FALSE.</code>, do not update <i>Q</i>;</p> <p>If <i>wantz</i> = <code>.TRUE.</code>, update the right transformation matrix <i>Z</i>;</p> <p>If <i>wantz</i> = <code>.FALSE.</code>, do not update <i>Z</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).</p>
<i>a, b, q,</i>	<p>REAL for <code>stgexc</code></p> <p>DOUBLE PRECISION for <code>dtgexc</code></p> <p>COMPLEX for <code>ctgexc</code></p> <p>DOUBLE COMPLEX for <code>ztgexc</code>.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) contains the matrix <i>A</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>b</i>(<i>ldb</i>,*) contains the matrix <i>B</i>. The second dimension of <i>b</i> must be at least $\max(1, n)$.</p> <p><i>q</i> (<i>ldq</i>,*)</p> <p>If <i>wantq</i> = <code>.FALSE.</code>, then <i>q</i> is not referenced.</p> <p>If <i>wantq</i> = <code>.TRUE.</code>, then <i>q</i> must contain the orthogonal/unitary matrix <i>Q</i>.</p> <p>The second dimension of <i>q</i> must be at least $\max(1, n)$.</p> <p><i>z</i> (<i>ldz</i>,*)</p> <p>If <i>wantz</i> = <code>.FALSE.</code>, then <i>z</i> is not referenced.</p> <p>If <i>wantz</i> = <code>.TRUE.</code>, then <i>z</i> must contain the orthogonal/unitary matrix <i>Z</i>.</p> <p>The second dimension of <i>z</i> must be at least $\max(1, n)$.</p>
<i>lda</i>	<p>INTEGER. The first dimension of <i>a</i>; at least $\max(1, n)$.</p>
<i>ldb</i>	<p>INTEGER. The first dimension of <i>b</i>; at least $\max(1, n)$.</p>
<i>ldq</i>	<p>INTEGER. The first dimension of <i>q</i>;</p> <p>If <i>wantq</i> = <code>.FALSE.</code>, then $ldq \geq 1$.</p> <p>If <i>wantq</i> = <code>.TRUE.</code>, then $ldq \geq \max(1, n)$.</p>
<i>ldz</i>	<p>INTEGER. The first dimension of <i>z</i>;</p> <p>If <i>wantz</i> = <code>.FALSE.</code>, then $ldz \geq 1$.</p>

	If <i>wantz</i> = <code>.TRUE.</code> , then $ldz \geq \max(1, n)$.
<i>ifst, ilst</i>	INTEGER. Specify the reordering of the diagonal blocks of (A, B) . The block with row index <i>ifst</i> is moved to row <i>ilst</i> , by a sequence of swapping between adjacent blocks. Constraint: $1 \leq ifst, ilst \leq n$.
<i>work</i>	REAL for <code>stgexc</code> ; DOUBLE PRECISION for <code>dtgexc</code> . Workspace array, DIMENSION (<i>lwork</i>). Used in real flavors only.
<i>lwork</i>	INTEGER. The dimension of <i>work</i> ; must be at least $4n + 16$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See <i>Application Notes</i> for details.

Output Parameters

<i>a, b</i>	Overwritten by the updated matrices <i>A</i> and <i>B</i> .
<i>ifst, ilst</i>	Overwritten for real flavors only. If <i>ifst</i> pointed to the second row of a 2 by 2 block on entry, it is changed to point to the first row; <i>ilst</i> always points to the first row of the block in its final position (which may differ from its input value by ± 1).
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill-conditioned. (A, B) may have been partially reordered, and <i>ilst</i> points to the first row of the current position of the block being moved.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgexc` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>b</code>	Holds the matrix B of size (n, n) .
<code>z</code>	Holds the matrix Z of size (n, n) .
<code>q</code>	Holds the matrix Q of size (n, n) .
<code>wantq</code>	Restored based on the presence of the argument <code>q</code> as follows: <code>wantq</code> = <code>.TRUE</code> , if <code>q</code> is present, <code>wantq</code> = <code>.FALSE</code> , if <code>q</code> is omitted.
<code>wantz</code>	Restored based on the presence of the argument <code>z</code> as follows: <code>wantz</code> = <code>.TRUE</code> , if <code>z</code> is present, <code>wantz</code> = <code>.FALSE</code> , if <code>z</code> is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of `lwork` for the first run, or set `lwork` = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array `work` on exit. Use this value (`work(1)`) for subsequent runs.

If `lwork` = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if `lwork` is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tgsen

Reorders the generalized Schur decomposition of a pair of matrices (A,B) so that a selected cluster of eigenvalues appears in the leading diagonal blocks of (A,B) .

Syntax

FORTRAN 77:

```
call stgsen(ijob, wantq, wantz, select, n, a, lda, b, ldb, alphas, alphas,
beta, q, ldq, z, ldz, m, pl, pr, dif, work, lwork, iwork, liwork, info)
call dtgsen(ijob, wantq, wantz, select, n, a, lda, b, ldb, alphas, alphas,
beta, q, ldq, z, ldz, m, pl, pr, dif, work, lwork, iwork, liwork, info)
call ctgsen(ijob, wantq, wantz, select, n, a, lda, b, ldb, alpha, beta, q,
ldq, z, ldz, m, pl, pr, dif, work, lwork, iwork, liwork, info)
call ztgsen(ijob, wantq, wantz, select, n, a, lda, b, ldb, alpha, beta, q,
ldq, z, ldz, m, pl, pr, dif, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call tgsen(a, b, select [,alphas] [,alphas] [,beta] [,ijob] [,q] [,z] [,pl]
[,pr] [,dif] [,m] [,info])
call tgsen(a, b, select [,alpha] [,beta] [,ijob] [,q] [,z] [,pl] [,pr] [, dif]
[,m] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine reorders the generalized real-Schur/Schur decomposition of a real/complex matrix pair (A, B) (in terms of an orthogonal/unitary equivalence transformation $Q^*(A,B)Z$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A, B)). The leading columns of Q and Z form orthonormal/unitary bases of the corresponding left and right eigenspaces (deflating subspaces).

(A, B) must be in generalized real-Schur/Schur canonical form (as returned by `?gges`), that is, A and B are both upper triangular.

?tgsen also computes the generalized eigenvalues

$\omega_j = (\text{alphar}(j) + \text{alphai}(j)*i)/\text{beta}(j)$ (for real flavors)

$\omega_j = \text{alpha}(j)/\text{beta}(j)$ (for complex flavors)

of the reordered matrix pair (A, B) .

Optionally, the routine computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are $\text{Difu}[(A_{11}, B_{11}), (A_{22}, B_{22})]$ and $\text{Difl}[(A_{11}, B_{11}), (A_{22}, B_{22})]$, that is, the separation(s) between the matrix pairs (A_{11}, B_{11}) and (A_{22}, B_{22}) that correspond to the selected cluster and the eigenvalues outside the cluster, respectively, and norms of "projections" onto left and right eigenspaces with respect to the selected cluster in the (1,1)-block.

Input Parameters

<i>ijob</i>	<p>INTEGER. Specifies whether condition numbers are required for the cluster of eigenvalues (<i>p1</i> and <i>pr</i>) or the deflating subspaces <i>Difu</i> and <i>Difl</i>.</p> <p>If <i>ijob</i> =0, only reorder with respect to <i>select</i>;</p> <p>If <i>ijob</i> =1, reciprocal of norms of "projections" onto left and right eigenspaces with respect to the selected cluster (<i>p1</i> and <i>pr</i>);</p> <p>If <i>ijob</i> =2, compute upper bounds on <i>Difu</i> and <i>Difl</i>, using F-norm-based estimate (<i>dif</i> (1:2));</p> <p>If <i>ijob</i> =3, compute estimate of <i>Difu</i> and <i>Difl</i>, using 1-norm-based estimate (<i>dif</i> (1:2)). This option is about 5 times as expensive as <i>ijob</i> =2;</p> <p>If <i>ijob</i> =4, compute <i>p1</i>, <i>pr</i> and <i>dif</i> (i.e., options 0, 1 and 2 above). This is an economic version to get it all;</p> <p>If <i>ijob</i> =5, compute <i>p1</i>, <i>pr</i> and <i>dif</i> (i.e., options 0, 1 and 3 above).</p>
<i>wantq, wantz</i>	<p>LOGICAL.</p> <p>If <i>wantq</i> = .TRUE., update the left transformation matrix <i>Q</i>;</p> <p>If <i>wantq</i> = .FALSE., do not update <i>Q</i>;</p> <p>If <i>wantz</i> = .TRUE., update the right transformation matrix <i>Z</i>;</p> <p>If <i>wantz</i> = .FALSE., do not update <i>Z</i>.</p>
<i>select</i>	<p>LOGICAL.</p>

Array, DIMENSION at least $\max(1, n)$. Specifies the eigenvalues in the selected cluster.
 To select an eigenvalue $\omega(j)$, $\text{select}(j)$ must be `.TRUE.` For real flavors: to select a complex conjugate pair of eigenvalues $\omega(j)$ and $\omega(j+1)$ (corresponding 2 by 2 diagonal block), $\text{select}(j)$ and/or $\text{select}(j+1)$ must be set to `.TRUE.`; the complex conjugate $\omega(j)$ and $\omega(j+1)$ must be either both included in the cluster or both excluded.

n INTEGER. The order of the matrices A and B ($n \geq 0$).

$a, b, q, z, work$ REAL for `stgsen`
 DOUBLE PRECISION for `dtgsen`
 COMPLEX for `ctgsen`
 DOUBLE COMPLEX for `ztgsen`.

Arrays:
 $a(lda,*)$ contains the matrix A .
 For real flavors: A is upper quasi-triangular, with (A, B) in generalized real Schur canonical form.
 For complex flavors: A is upper triangular, in generalized Schur canonical form.
 The second dimension of a must be at least $\max(1, n)$.
 $b(l db,*)$ contains the matrix B .
 For real flavors: B is upper triangular, with (A, B) in generalized real Schur canonical form.
 For complex flavors: B is upper triangular, in generalized Schur canonical form. The second dimension of b must be at least $\max(1, n)$.
 $q(ldq,*)$
 If $wantq = \text{.TRUE.}$, then q is an n -by- n matrix;
 If $wantq = \text{.FALSE.}$, then q is not referenced.
 The second dimension of q must be at least $\max(1, n)$.
 $z(ldz,*)$
 If $wantz = \text{.TRUE.}$, then z is an n -by- n matrix;
 If $wantz = \text{.FALSE.}$, then z is not referenced.
 The second dimension of z must be at least $\max(1, n)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of a ; at least $\max(1, n)$.

<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; at least $\max(1, n)$.
<i>ldq</i>	INTEGER. The first dimension of <i>q</i> ; $ldq \geq 1$. If <i>wantq</i> = <code>.TRUE.</code> , then $ldq \geq \max(1, n)$.
<i>ldz</i>	INTEGER. The first dimension of <i>z</i> ; $ldz \geq 1$. If <i>wantz</i> = <code>.TRUE.</code> , then $ldz \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . <i>For real flavors:</i> If <i>ijob</i> = 1, 2, or 4, $lwork \geq \max(4n+16, 2m(n-m))$. If <i>ijob</i> = 3 or 5, $lwork \geq \max(4n+16, 4m(n-m))$. <i>For complex flavors:</i> If <i>ijob</i> = 1, 2, or 4, $lwork \geq \max(1, 2m(n-m))$. If <i>ijob</i> = 3 or 5, $lwork \geq \max(1, 4m(n-m))$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for details.
<i>iwork</i>	INTEGER. Workspace array, its dimension $\max(1, liwork)$. If <i>ijob</i> = 0, <i>iwork</i> is not referenced.
<i>liwork</i>	INTEGER. The dimension of the array <i>iwork</i> . <i>For real flavors:</i> If <i>ijob</i> = 1, 2, or 4, $liwork \geq n+6$. If <i>ijob</i> = 3 or 5, $liwork \geq \max(n+6, 2m(n-m))$. <i>For complex flavors:</i> If <i>ijob</i> = 1, 2, or 4, $liwork \geq n+2$. If <i>ijob</i> = 3 or 5, $liwork \geq \max(n+2, 2m(n-m))$. If <i>liwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>iwork</i> array, returns this value as the first entry of the <i>iwork</i> array, and no error message related to <i>liwork</i> is issued by xerbla . See <i>Application Notes</i> for details.

Output Parameters

<i>a, b</i>	Overwritten by the reordered matrices <i>A</i> and <i>B</i> , respectively.
<i>alphar, alphas</i>	REAL for <i>stgsen</i> ; DOUBLE PRECISION for <i>dtgsen</i> . Arrays, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in real flavors. See <i>beta</i> .
<i>alpha</i>	COMPLEX for <i>ctgsen</i> ; DOUBLE COMPLEX for <i>ztgsen</i> . Array, DIMENSION at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i> .
<i>beta</i>	REAL for <i>stgsen</i> DOUBLE PRECISION for <i>dtgsen</i> COMPLEX for <i>ctgsen</i> DOUBLE COMPLEX for <i>ztgsen</i> . Array, DIMENSION at least $\max(1, n)$. <i>For real flavors:</i> On exit, $(\text{alphar}(j) + \text{alphas}(j)*i)/\text{beta}(j)$, $j=1, \dots, n$, will be the generalized eigenvalues. $\text{alphar}(j) + \text{alphas}(j)*i$ and $\text{beta}(j)$, $j=1, \dots, n$ are the diagonals of the complex Schur form (<i>S,T</i>) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (<i>A,B</i>) were further reduced to triangular form using complex unitary transformations. If $\text{alphas}(j)$ is zero, then the <i>j</i> -th eigenvalue is real; if positive, then the <i>j</i> -th and (<i>j</i> +1)-st eigenvalues are a complex conjugate pair, with $\text{alphas}(j+1)$ negative. <i>For complex flavors:</i> The diagonal elements of <i>A</i> and <i>B</i> , respectively, when the pair (<i>A,B</i>) has been reduced to generalized Schur form. $\text{alpha}(i)/\text{beta}(i)$, $i=1, \dots, n$ are the generalized eigenvalues.

<i>q</i>	If <i>wantq</i> = .TRUE., then, on exit, <i>Q</i> has been postmultiplied by the left orthogonal transformation matrix which reorder (<i>A</i> , <i>B</i>). The leading <i>m</i> columns of <i>Q</i> form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces).
<i>z</i>	If <i>wantz</i> = .TRUE., then, on exit, <i>Z</i> has been postmultiplied by the left orthogonal transformation matrix which reorder (<i>A</i> , <i>B</i>). The leading <i>m</i> columns of <i>Z</i> form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces).
<i>m</i>	INTEGER. The dimension of the specified pair of left and right eigen-spaces (deflating subspaces); $0 \leq m \leq n$.
<i>pl, pr</i>	REAL for single precision flavors; DOUBLE PRECISION for double precision flavors. If <i>ijob</i> = 1, 4, or 5, <i>pl</i> and <i>pr</i> are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspaces with respect to the selected cluster. $0 < pl, pr \leq 1$. If <i>m</i> = 0 or <i>m</i> = <i>n</i> , <i>pl</i> = <i>pr</i> = 1. If <i>ijob</i> = 0, 2 or 3, <i>pl</i> and <i>pr</i> are not referenced
<i>dif</i>	REAL for single precision flavors; DOUBLE PRECISION for double precision flavors. Array, DIMENSION (2). If <i>ijob</i> ≥ 2, <i>dif</i> (1:2) store the estimates of <i>Difu</i> and <i>Difl</i> . If <i>ijob</i> = 2 or 4, <i>dif</i> (1:2) are F-norm-based upper bounds on <i>Difu</i> and <i>Difl</i> . If <i>ijob</i> = 3 or 5, <i>dif</i> (1:2) are 1-norm-based estimates of <i>Difu</i> and <i>Difl</i> . If <i>m</i> = 0 or <i>n</i> , <i>dif</i> (1:2) = F-norm([<i>A</i> , <i>B</i>]). If <i>ijob</i> = 0 or 1, <i>dif</i> is not referenced.
<i>work</i> (1)	If <i>ijob</i> is not 0 and <i>info</i> = 0, on exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.

<i>iwork</i> (1)	If <i>ijob</i> is not 0 and <i>info</i> = 0, on exit, <i>iwork</i> (1) contains the minimum value of <i>liwork</i> required for optimum performance. Use this <i>liwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, Reordering of (<i>A</i> , <i>B</i>) failed because the transformed matrix pair (<i>A</i> , <i>B</i>) would be too far from generalized Schur form; the problem is very ill-conditioned. (<i>A</i> , <i>B</i>) may have been partially reordered. If requested, 0 is returned in <i>dif</i> (*), <i>p1</i> and <i>pr</i> .

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgseqn` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>n</i> , <i>n</i>).
<i>select</i>	Holds the vector of length <i>n</i> .
<i>alphar</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alphai</i>	Holds the vector of length <i>n</i> . Used in real flavors only.
<i>alpha</i>	Holds the vector of length <i>n</i> . Used in complex flavors only.
<i>beta</i>	Holds the vector of length <i>n</i> .
<i>q</i>	Holds the matrix <i>Q</i> of size (<i>n</i> , <i>n</i>).
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>).
<i>dif</i>	Holds the vector of length (2).
<i>ijob</i>	Must be 0, 1, 2, 3, 4, or 5. The default value is 0.
<i>wantq</i>	Restored based on the presence of the argument <i>q</i> as follows: <i>wantq</i> = .TRUE, if <i>q</i> is present, <i>wantq</i> = .FALSE, if <i>q</i> is omitted.
<i>wantz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>wantz</i> = .TRUE, if <i>z</i> is present, <i>wantz</i> = .FALSE, if <i>z</i> is omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* (or *liwork*) for the first run or set *lwork* = -1 (*liwork* = -1).

If *lwork* (or *liwork*) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*) on exit. Use this value (*work*(1), *iwork*(1)) for subsequent runs.

If *lwork* = -1 (*liwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*). This operation is called a workspace query.

Note that if *lwork* (*liwork*) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tgsyl

Solves the generalized Sylvester equation.

Syntax

FORTRAN 77:

```
call stgsyl(trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,  
scale, dif, work, lwork, iwork, info)
```

```
call dtgsyl(trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,  
scale, dif, work, lwork, iwork, info)
```

```
call ctgsyl(trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,  
scale, dif, work, lwork, iwork, info)
```

```
call ztgsyl(trans, ijob, m, n, a, lda, b, ldb, c, ldc, d, ldd, e, lde, f, ldf,  
scale, dif, work, lwork, iwork, info)
```

Fortran 95:

```
call tgsyl(a, b, c, d, e, f [,ijob] [,trans] [,scale] [,dif] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves the generalized Sylvester equation:

$$A^*R - L^*B = scale^*C$$

$$D^*R - L^*E = scale^*F$$

where R and L are unknown m -by- n matrices, (A, D) , (B, E) and (C, F) are given matrix pairs of size m -by- m , n -by- n and m -by- n , respectively, with real/complex entries. (A, D) and (B, E) must be in generalized real-Schur/Schur canonical form, that is, A, B are upper quasi-triangular/triangular and D, E are upper triangular.

The solution (R, L) overwrites (C, F) . The factor $scale$, $0 \leq scale \leq 1$, is an output scaling factor chosen to avoid overflow.

In matrix notation the above equation is equivalent to the following: solve $Z^*x = scale^*b$, where Z is defined as

$$Z = \begin{pmatrix} kron(I_n, A) - kron(B', I_m) \\ kron(I_n, D) - kron(E', I_m) \end{pmatrix}$$

Here I_k is the identity matrix of size k and x' is the transpose/conjugate-transpose of x . $kron(X, Y)$ is the Kronecker product between the matrices X and Y .

If $trans = 'T'$ (for real flavors), or $trans = 'C'$ (for complex flavors), the routine `?tgsyl` solves the transposed/conjugate-transposed system $Z'^*y = scale^*b$, which is equivalent to solve for R and L in

$$A'^*R + D'^*L = scale^*C$$

$$R^*B' + L^*E' = scale^*(-F)$$

This case ($trans = 'T'$ for `stgsyl/dtgsyl` or $trans = 'C'$ for `ctgsyl/ztgsyl`) is used to compute an one-norm-based estimate of $Dif[(A, D), (B, E)]$, the separation between the matrix pairs (A, D) and (B, E) , using [slacon/clacon](#).

If $ijob \geq 1$, `?tgsyl` computes a Frobenius norm-based estimate of $Dif[(A, D), (B, E)]$. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z . This is a level 3 BLAS algorithm.

Input Parameters

<i>trans</i>	<p>CHARACTER*1. Must be 'N', 'T', or 'C'.</p> <p>If <i>trans</i> = 'N', solve the generalized Sylvester equation.</p> <p>If <i>trans</i> = 'T', solve the 'transposed' system (for real flavors only).</p> <p>If <i>trans</i> = 'C', solve the 'conjugate transposed' system (for complex flavors only).</p>
<i>ijob</i>	<p>INTEGER. Specifies what kind of functionality to be performed:</p> <p>If <i>ijob</i> = 0, solve the generalized Sylvester equation only;</p> <p>If <i>ijob</i> = 1, perform the functionality of <i>ijob</i> = 0 and <i>ijob</i> = 3;</p> <p>If <i>ijob</i> = 2, perform the functionality of <i>ijob</i> = 0 and <i>ijob</i> = 4;</p> <p>If <i>ijob</i> = 3, only an estimate of $\text{Dif}[(A, D), (B, E)]$ is computed (look ahead strategy is used);</p> <p>If <i>ijob</i> = 4, only an estimate of $\text{Dif}[(A, D), (B, E)]$ is computed (?gecon on sub-systems is used). If <i>trans</i> = 'T' or 'C', <i>ijob</i> is not referenced.</p>
<i>m</i>	<p>INTEGER. The order of the matrices <i>A</i> and <i>D</i>, and the row dimension of the matrices <i>C</i>, <i>F</i>, <i>R</i> and <i>L</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrices <i>B</i> and <i>E</i>, and the column dimension of the matrices <i>C</i>, <i>F</i>, <i>R</i> and <i>L</i>.</p>
<i>a, b, c, d, e, f, work</i>	<p>REAL for stgsyl DOUBLE PRECISION for dtgsyl COMPLEX for ctgsyl DOUBLE COMPLEX for ztgsyl.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix <i>A</i>. The second dimension of <i>a</i> must be at least $\max(1, m)$.</p> <p><i>b</i>(<i>ldb</i>,*) contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix <i>B</i>. The second dimension of <i>b</i> must be at least $\max(1, n)$.</p> <p><i>c</i> (<i>ldc</i>,*) contains the right-hand-side of the first matrix equation in the generalized Sylvester equation (as defined by <i>trans</i>)</p>

The second dimension of c must be at least $\max(1, n)$.
 d ($ldd, *$) contains the upper triangular matrix D .
The second dimension of d must be at least $\max(1, m)$.
 e ($lde, *$) contains the upper triangular matrix E .
The second dimension of e must be at least $\max(1, n)$.
 f ($ldf, *$) contains the right-hand-side of the second matrix equation in the generalized Sylvester equation (as defined by $trans$)
The second dimension of f must be at least $\max(1, n)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.

lda INTEGER. The first dimension of a ; at least $\max(1, m)$.
 ldb INTEGER. The first dimension of b ; at least $\max(1, n)$.
 ldc INTEGER. The first dimension of c ; at least $\max(1, m)$.
 ldd INTEGER. The first dimension of d ; at least $\max(1, m)$.
 lde INTEGER. The first dimension of e ; at least $\max(1, n)$.
 ldf INTEGER. The first dimension of f ; at least $\max(1, m)$.
 $lwork$ INTEGER.

The dimension of the array $work$. $lwork \geq 1$.

If $ijob = 1$ or 2 and $trans = 'N'$, $lwork \geq \max(1, 2*m*n)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by [xerbla](#). See *Application Notes* for details.

$iwork$ INTEGER. Workspace array, DIMENSION at least $(m+n+6)$ for real flavors, and at least $(m+n+2)$ for complex flavors.

Output Parameters

c If $ijob=0, 1,$ or 2 , overwritten by the solution R .
If $ijob=3$ or 4 and $trans = 'N'$, c holds R , the solution achieved during the computation of the Dif-estimate.

f If $ijob=0, 1,$ or 2 , overwritten by the solution L .

	<p>If $ijob=3$ or 4 and $trans = 'N'$, f holds L, the solution achieved during the computation of the Dif-estimate.</p>
<i>dif</i>	<p>REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. On exit, <i>dif</i> is the reciprocal of a lower bound of the reciprocal of the Dif-function, that is, <i>dif</i> is an upper bound of $\text{Dif}[(A, D), (B, E)] = \text{sigma_min}(Z)$, where Z as in (2). If $ijob = 0$, or $trans = 'T'$ (for real flavors), or $trans = 'C'$ (for complex flavors), <i>dif</i> is not touched.</p>
<i>scale</i>	<p>REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. On exit, <i>scale</i> is the scaling factor in the generalized Sylvester equation. If $0 < scale < 1$, c and f hold the solutions R and L, respectively, to a slightly perturbed system but the input matrices A, B, D and E have not been changed. If $scale = 0$, c and f hold the solutions R and L, respectively, to the homogeneous system with $C = F = 0$. Normally, $scale = 1$.</p>
<i>work(1)</i>	<p>If $info = 0$, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.</p>
<i>info</i>	<p>INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i-th parameter had an illegal value. If $info > 0$, (A, D) and (B, E) have common or close eigenvalues.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tg syl` interface are the following:

<i>a</i>	Holds the matrix A of size (m, m) .
<i>b</i>	Holds the matrix B of size (n, n) .

<i>c</i>	Holds the matrix <i>C</i> of size (m, n) .
<i>d</i>	Holds the matrix <i>D</i> of size (m, m) .
<i>e</i>	Holds the matrix <i>E</i> of size (n, n) .
<i>f</i>	Holds the matrix <i>F</i> of size (m, n) .
<i>ijob</i>	Must be 0, 1, 2, 3, or 4. The default value is 0.
<i>trans</i>	Must be 'N' or 'T'. The default value is 'N'.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?tgsna

Estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a pair of matrices in generalized real Schur canonical form.

Syntax

FORTRAN 77:

```
call stgsna(job, howmny, select, n, a, lda, b, ldb, vl, ldvl, vr, ldvr, s,
dif, mm, m, work, lwork, iwork, info)

call dtgsna(job, howmny, select, n, a, lda, b, ldb, vl, ldvl, vr, ldvr, s,
dif, mm, m, work, lwork, iwork, info)

call ctgsna(job, howmny, select, n, a, lda, b, ldb, vl, ldvl, vr, ldvr, s,
dif, mm, m, work, lwork, iwork, info)
```

```
call ztgsna(job, howmny, select, n, a, lda, b, ldb, vl, ldvl, vr, ldvr, s,
dif, mm, m, work, lwork, iwork, info)
```

Fortran 95:

```
call tgsna(a, b [,s] [,dif] [,vl] [,vr] [,select] [,m] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The real flavors `stgsna/dtgsna` of this routine estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair $(Q^*A^*Z^T, Q^*B^*Z^T)$ with orthogonal matrices Q and Z).

(A, B) must be in generalized real Schur form (as returned by `srges/drges`), that is, A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

The complex flavors `ctgsna/ztgsna` estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) . (A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Input Parameters

<i>job</i>	CHARACTER*1. Specifies whether condition numbers are required for eigenvalues or eigenvectors. Must be 'E' or 'V' or 'B'. If <i>job</i> = 'E', for eigenvalues only (compute <i>s</i>). If <i>job</i> = 'V', for eigenvectors only (compute <i>dif</i>). If <i>job</i> = 'B', for both eigenvalues and eigenvectors (compute both <i>s</i> and <i>dif</i>).
<i>howmny</i>	CHARACTER*1. Must be 'A' or 'S'. If <i>howmny</i> = 'A', compute condition numbers for all eigenpairs. If <i>howmny</i> = 'S', compute condition numbers for selected eigenpairs specified by the logical array <i>select</i> .
<i>select</i>	LOGICAL. Array, DIMENSION at least $\max(1, n)$. If <i>howmny</i> = 'S', <i>select</i> specifies the eigenpairs for which condition numbers are required. If <i>howmny</i> = 'A', <i>select</i> is not referenced. <i>For real flavors:</i>

To select condition numbers for the eigenpair corresponding to a real eigenvalue $\omega(j)$, $select(j)$ must be set to `.TRUE.`; to select condition numbers corresponding to a complex conjugate pair of eigenvalues $\omega(j)$ and $\omega(j+1)$, either $select(j)$ or $select(j+1)$ must be set to `.TRUE.`

For complex flavors:

To select condition numbers for the corresponding j -th eigenvalue and/or eigenvector, $select(j)$ must be set to `.TRUE.`

n INTEGER. The order of the square matrix pair (A, B) ($n \geq 0$).

$a, b, v1, vr, work$ REAL for `stgsna`
DOUBLE PRECISION for `dtgsna`
COMPLEX for `ctgsna`
DOUBLE COMPLEX for `ztgsna`.

Arrays:
 $a(lda,*)$ contains the upper quasi-triangular (for real flavors) or upper triangular (for complex flavors) matrix A in the pair (A, B) .
The second dimension of a must be at least $\max(1, n)$.
 $b(l db,*)$ contains the upper triangular matrix B in the pair (A, B) . The second dimension of b must be at least $\max(1, n)$.
If $job = 'E'$ or $'B'$, $v1(ldv1,*)$ must contain left eigenvectors of (A, B) , corresponding to the eigenpairs specified by $howmny$ and $select$. The eigenvectors must be stored in consecutive columns of $v1$, as returned by `?tgevc`.
If $job = 'V'$, $v1$ is not referenced. The second dimension of $v1$ must be at least $\max(1, m)$.
If $job = 'E'$ or $'B'$, $vr(ldvr,*)$ must contain right eigenvectors of (A, B) , corresponding to the eigenpairs specified by $howmny$ and $select$. The eigenvectors must be stored in consecutive columns of vr , as returned by `?tgevc`.
If $job = 'V'$, vr is not referenced. The second dimension of vr must be at least $\max(1, m)$.
 $work$ is a workspace array, its dimension $\max(1, lwork)$.

	If <i>job</i> = 'E', <i>work</i> is not referenced.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; at least $\max(1, n)$.
<i>ldv1</i>	INTEGER. The first dimension of <i>v1</i> ; $ldv1 \geq 1$. If <i>job</i> = 'E' or 'B', then $ldv1 \geq \max(1, n)$.
<i>ldvr</i>	INTEGER. The first dimension of <i>vr</i> ; $ldvr \geq 1$. If <i>job</i> = 'E' or 'B', then $ldvr \geq \max(1, n)$.
<i>mm</i>	INTEGER. The number of elements in the arrays <i>s</i> and <i>dif</i> ($mm \geq m$).
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . $lwork \geq \max(1, n)$. If <i>job</i> = 'V' or 'B', $lwork \geq 2*n*(n+2)+16$ for real flavors, and $lwork \geq \max(1, 2*n*n)$ for complex flavors. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for details.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $(n+6)$ for real flavors, and at least $(n+2)$ for complex flavors. If <i>job</i> = 'E', <i>iwork</i> is not referenced.

Output Parameters

<i>s</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. Array, DIMENSION (<i>mm</i>). If <i>job</i> = 'E' or 'B', contains the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If <i>job</i> = 'V', <i>s</i> is not referenced. <i>For real flavors:</i>
----------	---

For a complex conjugate pair of eigenvalues two consecutive elements of s are set to the same value. Thus, $s(j)$, $dif(j)$, and the j -th columns of v_l and v_r all correspond to the same eigenpair (but not in general the j -th eigenpair, unless all eigenpairs are selected).

dif REAL for single-precision flavors
DOUBLE PRECISION for double-precision flavors.
Array, DIMENSION (mm).
If $job = 'V'$ or $'B'$, contains the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array.
If the eigenvalues cannot be reordered to compute $dif(j)$, $dif(j)$ is set to 0; this can only occur when the true value would be very small anyway.
If $job = 'E'$, dif is not referenced.
For real flavors:
For a complex eigenvector, two consecutive elements of dif are set to the same value.
For complex flavors:
For each eigenvalue/vector specified by $select$, dif stores a Frobenius norm-based estimate of $Difl$.

m INTEGER. The number of elements in the arrays s and dif used to store the specified condition numbers; for each selected eigenvalue one element is used.
If $howmny = 'A'$, m is set to n .

work(1) *work(1)*
If job is not $'E'$ and $info = 0$, on exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

info INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgsna` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (n, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (n, n) .
<i>s</i>	Holds the vector of length (mm) .
<i>dif</i>	Holds the vector of length (mm) .
<i>vl</i>	Holds the matrix <i>VL</i> of size (n, mm) .
<i>vr</i>	Holds the matrix <i>VR</i> of size (n, mm) .
<i>select</i>	Holds the vector of length <i>n</i> .
<i>howmny</i>	Restored based on the presence of the argument <i>select</i> as follows: <i>howmny</i> = 'S', if <i>select</i> is present, <i>howmny</i> = 'A', if <i>select</i> is omitted.
<i>job</i>	Restored based on the presence of arguments <i>s</i> and <i>dif</i> as follows: <i>job</i> = 'B', if both <i>s</i> and <i>dif</i> are present, <i>job</i> = 'E', if <i>s</i> is present and <i>dif</i> omitted, <i>job</i> = 'V', if <i>s</i> is omitted and <i>dif</i> present, Note that there will be an error condition if both <i>s</i> and <i>dif</i> are omitted.

Application Notes

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

In first case the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Generalized Singular Value Decomposition

This section describes LAPACK computational routines used for finding the generalized singular value decomposition (GSVD) of two matrices *A* and *B* as

$$U^H A Q = D_1 * (0 \ R),$$

$$V^H B Q = D_2^* (O R),$$

where U , V , and Q are orthogonal/unitary matrices, R is a nonsingular upper triangular matrix, and D_1 , D_2 are “diagonal” matrices of the structure detailed in the routines description section.

Table 4-7 lists LAPACK routines (FORTRAN 77 interface) that perform generalized singular value decomposition of matrices. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-7 Computational Routines for Generalized Singular Value Decomposition

Routine name	Operation performed
?ggsvp	Computes the preprocessing decomposition for the generalized SVD
?tgsja	Computes the generalized SVD of two upper triangular or trapezoidal matrices

You can use routines listed in the above table as well as the driver routine ?ggsvd to find the GSVD of a pair of general rectangular matrices.

?ggsvp

Computes the preprocessing decomposition for the generalized SVD.

Syntax

FORTRAN 77:

```
call sggsvp(jobu, jobv, jobq, m, p, n, a, lda, b, ldb, tola, tolb, k, l, u,
ldu, v, ldv, q, ldq, iwork, tau, work, info)

call dggsvp(jobu, jobv, jobq, m, p, n, a, lda, b, ldb, tola, tolb, k, l, u,
ldu, v, ldv, q, ldq, iwork, tau, work, info)

call cggsvp(jobu, jobv, jobq, m, p, n, a, lda, b, ldb, tola, tolb, k, l, u,
ldu, v, ldv, q, ldq, iwork, rwork, tau, work, info)

call zggsvp(jobu, jobv, jobq, m, p, n, a, lda, b, ldb, tola, tolb, k, l, u,
ldu, v, ldv, q, ldq, iwork, rwork, tau, work, info)
```

Fortran 95:

```
call ggsvp(a, b, tola, tolb [, k] [,l] [,u] [,v] [,q] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes orthogonal matrices u , v and q such that

$$U^H A Q = \begin{matrix} & n-k-l & k & l \\ & k & & \\ & l & & \\ m-k-l & & & \end{matrix} \begin{pmatrix} \mathbf{0} & A_{12} & A_{13} \\ \mathbf{0} & \mathbf{0} & A_{23} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} \end{pmatrix}, \quad \text{if } m-k-l \geq 0$$

$$= \begin{matrix} & n-k-l & k & l \\ & k & & \\ m-k & & & \end{matrix} \begin{pmatrix} \mathbf{0} & A_{12} & A_{13} \\ \mathbf{0} & \mathbf{0} & A_{23} \end{pmatrix}, \quad \text{if } m-k-l < 0$$

$$V^H B Q = \begin{matrix} & n-k-l & k & l \\ & l & & \\ p-l & & & \end{matrix} \begin{pmatrix} \mathbf{0} & \mathbf{0} & B_{13} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} \end{pmatrix}$$

where the k -by- k matrix A_{12} and l -by- l matrix B_{13} are nonsingular upper triangular; A_{23} is l -by- l upper triangular if $m-k-l \geq 0$, otherwise A_{23} is $(m-k)$ -by- l upper trapezoidal. The sum $k+1$ is equal to the effective numerical rank of the $(m+p)$ -by- n matrix $(A^H, B^H)^H$.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine [?ggsvd](#).

Input Parameters

<i>jobu</i>	CHARACTER*1. Must be 'U' or 'N'. If <i>jobu</i> = 'U', orthogonal/unitary matrix <i>U</i> is computed. If <i>jobu</i> = 'N', <i>U</i> is not computed.
<i>jobv</i>	CHARACTER*1. Must be 'V' or 'N'. If <i>jobv</i> = 'V', orthogonal/unitary matrix <i>V</i> is computed. If <i>jobv</i> = 'N', <i>V</i> is not computed.
<i>jobq</i>	CHARACTER*1. Must be 'Q' or 'N'. If <i>jobq</i> = 'Q', orthogonal/unitary matrix <i>Q</i> is computed. If <i>jobq</i> = 'N', <i>Q</i> is not computed.
<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ($m \geq 0$).
<i>p</i>	INTEGER. The number of rows of the matrix <i>B</i> ($p \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>a, b, tau, work</i>	REAL for sggsvp DOUBLE PRECISION for dggsvp COMPLEX for cggsvp DOUBLE COMPLEX for zggsvp. Arrays: <i>a</i> (<i>lda</i> ,*) contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb</i> ,*) contains the <i>p</i> -by- <i>n</i> matrix <i>B</i> . The second dimension of <i>b</i> must be at least $\max(1, n)$. <i>tau</i> (*) is a workspace array. The dimension of <i>tau</i> must be at least $\max(1, n)$. <i>work</i> (*) is a workspace array. The dimension of <i>work</i> must be at least $\max(1, 3n, m, p)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; at least $\max(1, p)$.
<i>tola, tolb</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. <i>tola</i> and <i>tolb</i> are the thresholds to determine the effective numerical rank of matrix <i>B</i> and a subblock of <i>A</i> . Generally, they are set to $tola = \max(m, n) * A * \text{MACHEPS}$,

$tolb = \max(p, n) * ||B|| * \text{MACHEPS}$.

The size of $tola$ and $tolb$ may affect the size of backward errors of the decomposition.

ldu	INTEGER. The first dimension of the output array u . $ldu \geq \max(1, m)$ if $jobu = 'U'$; $ldu \geq 1$ otherwise.
ldv	INTEGER. The first dimension of the output array v . $ldv \geq \max(1, p)$ if $jobv = 'V'$; $ldv \geq 1$ otherwise.
ldq	INTEGER. The first dimension of the output array q . $ldq \geq \max(1, n)$ if $jobq = 'Q'$; $ldq \geq 1$ otherwise.
$iwork$	INTEGER. Workspace array, DIMENSION at least $\max(1, n)$.
$rwork$	REAL for cggsvp DOUBLE PRECISION for zggsvp. Workspace array, DIMENSION at least $\max(1, 2n)$. Used in complex flavors only.

Output Parameters

a	Overwritten by the triangular (or trapezoidal) matrix described in the <i>Description</i> section.
b	Overwritten by the triangular matrix described in the <i>Description</i> section.
k, l	INTEGER. On exit, k and l specify the dimension of subblocks. The sum $k + l$ is equal to effective numerical rank of $(A^H, B^H)^H$.
u, v, q	REAL for sggsvp DOUBLE PRECISION for dggsvp COMPLEX for cggsvp DOUBLE COMPLEX for zggsvp. Arrays: If $jobu = 'U'$, $u(ldu,*)$ contains the orthogonal/unitary matrix U . The second dimension of u must be at least $\max(1, m)$. If $jobu = 'N'$, u is not referenced. If $jobv = 'V'$, $v(ldv,*)$ contains the orthogonal/unitary matrix V . The second dimension of v must be at least $\max(1, m)$.

If $jobv = 'N'$, v is not referenced.
 If $jobq = 'Q'$, $q(ldq,*)$ contains the orthogonal/unitary matrix Q .
 The second dimension of q must be at least $\max(1, n)$.
 If $jobq = 'N'$, q is not referenced.

info INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggsvp` interface are the following:

<i>a</i>	Holds the matrix A of size (m, n) .
<i>b</i>	Holds the matrix B of size (p, n) .
<i>u</i>	Holds the matrix U of size (m, m) .
<i>v</i>	Holds the matrix V of size (p, m) .
<i>q</i>	Holds the matrix Q of size (n, n) .
<i>jobu</i>	Restored based on the presence of the argument u as follows: $jobu = 'U'$, if u is present, $jobu = 'N'$, if u is omitted.
<i>jobv</i>	Restored based on the presence of the argument v as follows: $jobv = 'V'$, if v is present, $jobv = 'N'$, if v is omitted.
<i>jobq</i>	Restored based on the presence of the argument q as follows: $jobq = 'Q'$, if q is present, $jobq = 'N'$, if q is omitted.

?tgsja

Computes the generalized SVD of two upper triangular or trapezoidal matrices.

Syntax

FORTRAN 77:

```
call stgsja(jobu, jobv, jobq, m, p, n, k, l, a, lda, b, ldb, tola, tolb, alpha,
beta, u, ldu, v, ldv, q, ldq, work, ncycle, info)
```

```
call dtgsja(jobu, jobv, jobq, m, p, n, k, l, a, lda, b, ldb, tola, tolb, alpha,
beta, u, ldu, v, ldv, q, ldq, work, ncycle, info)
```

```
call ctgsja(jobu, jobv, jobq, m, p, n, k, l, a, lda, b, ldb, tola, tolb, alpha,
beta, u, ldu, v, ldv, q, ldq, work, ncycle, info)
```

```
call ztgsja(jobu, jobv, jobq, m, p, n, k, l, a, lda, b, ldb, tola, tolb, alpha,
beta, u, ldu, v, ldv, q, ldq, work, ncycle, info)
```

Fortran 95:

```
call tgsja(a, b, tola, tolb, k, l [,u] [,v] [,q] [,jobu] [,jobv] [,jobq]
[,alpha] [,beta] [,ncycle] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the generalized singular value decomposition (GSVD) of two real/complex upper triangular (or trapezoidal) matrices A and B . On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine [?ggsvp](#) from a general m -by- n matrix A and p -by- n matrix B :

$$A = \begin{matrix} & n-k-l & k & l \\ & k & \begin{pmatrix} 0 & A_{12} & A_{13} \\ 0 & 0 & A_{23} \\ 0 & 0 & 0 \end{pmatrix} \\ & l & \\ m-k-l & \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \end{matrix}, \quad \text{if } m-k-l \geq 0$$

$$= \begin{matrix} & n-k-l & k & l \\ & k & \begin{pmatrix} \mathbf{0} & A_{12} & A_{13} \\ \mathbf{0} & \mathbf{0} & A_{23} \end{pmatrix} & \end{matrix}, \quad \text{if } m-k-l < 0$$

$$B = \begin{matrix} & n-k-l & k & l \\ & l & \begin{pmatrix} \mathbf{0} & \mathbf{0} & B_{13} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} \end{pmatrix} & \\ p-l & \end{matrix}$$

where the k -by- k matrix A_{12} and l -by- l matrix B_{13} are nonsingular upper triangular; A_{23} is l -by- l upper triangular if $m-k-l \geq 0$, otherwise A_{23} is $(m-k)$ -by- l upper trapezoidal.

On exit,

$$U^H * A * Q = D_1 * (0 \ R), \quad V^H * B * Q = D_2 * (0 \ R),$$

where U , V and Q are orthogonal/unitary matrices, R is a nonsingular upper triangular matrix, and D_1 and D_2 are "diagonal" matrices, which are of the following structures:

If $m-k-l \geq 0$,

$$D_1 = \begin{matrix} & & k & l \\ & k & \begin{pmatrix} \mathbf{0} & \mathbf{0} \\ \mathbf{0} & C \\ \mathbf{0} & \mathbf{0} \end{pmatrix} & \\ m-k-l & \end{matrix}$$

$$D_1 = \begin{matrix} & & k & l \\ & & l & \\ & & \mathbf{0} & \mathbf{S} \\ p-l & & \mathbf{0} & \mathbf{0} \end{matrix}$$

$$(\mathbf{0} \ R) = \begin{matrix} & & n-k-l & k & l \\ & & k & \\ & & l & \\ & & \mathbf{0} & \mathbf{0} & \\ & & \mathbf{0} & R_{11} & R_{12} \\ & & \mathbf{0} & \mathbf{0} & R_{22} \end{matrix}$$

where

$$C = \text{diag}(\alpha(k+1), \dots, \alpha(k+1))$$

$$S = \text{diag}(\beta(k+1), \dots, \beta(k+1))$$

$$C^2 + S^2 = I$$

R is stored in $a(1:k+l, n-k-l+1:n)$ on exit.

If $m-k-l < 0$,

$$D_1 = \begin{matrix} & & k & m-l & k+l-m \\ & & k & \\ & & m-k & \\ & & \mathbf{0} & \mathbf{0} & \\ & & \mathbf{0} & C & \mathbf{0} \end{matrix}$$

$$D_2 = \begin{matrix} & k & m-k & k+l-m \\ m-k & \begin{pmatrix} 0 & S & 0 \\ 0 & 0 & I \\ p-l & 0 & 0 \end{pmatrix} \end{matrix}$$

$$(\mathbf{0} \ R) = \begin{matrix} & n-k-l & k & m-k & k+l-m \\ k & \begin{pmatrix} 0 & R_{11} & R_{12} & R_{13} \\ 0 & 0 & R_{22} & R_{23} \\ 0 & 0 & 0 & R_{33} \end{pmatrix} \\ m-k & & & & \\ k+l-m & & & & \end{matrix}$$

where

$C = \text{diag}(\alpha(K+1), \dots, \alpha(m)),$

$S = \text{diag}(\beta(K+1), \dots, \beta(m)),$

$C^2 + S^2 = I$

On exit, $\begin{pmatrix} R_{11} & R_{12} & R_{13} \\ \mathbf{0} & R_{22} & R_{23} \end{pmatrix}$ is stored in $a(1:m, n-k-l+1:n)$ and R_{33} is stored in $b(m-k+1:l, n+m-k-l+1:n)$.

The computation of the orthogonal/unitary transformation matrices U , V or Q is optional. These matrices may either be formed explicitly, or they *may* be postmultiplied into input matrices U_1 , V_1 , or Q_1 .

Input Parameters

jobu CHARACTER*1. Must be 'U', 'I', or 'N'.

If $jobu = 'U'$, u must contain an orthogonal/unitary matrix U_1 on entry.
 If $jobu = 'I'$, u is initialized to the unit matrix.
 If $jobu = 'N'$, u is not computed.

jobv CHARACTER*1. Must be 'V', 'I', or 'N'.
 If $jobv = 'V'$, v must contain an orthogonal/unitary matrix V_1 on entry.
 If $jobv = 'I'$, v is initialized to the unit matrix.
 If $jobv = 'N'$, v is not computed.

jobq CHARACTER*1. Must be 'Q', 'I', or 'N'.
 If $jobq = 'Q'$, q must contain an orthogonal/unitary matrix Q_1 on entry.
 If $jobq = 'I'$, q is initialized to the unit matrix.
 If $jobq = 'N'$, q is not computed.

m INTEGER. The number of rows of the matrix A ($m \geq 0$).

p INTEGER. The number of rows of the matrix B ($p \geq 0$).

n INTEGER. The number of columns of the matrices A and B ($n \geq 0$).

k, l INTEGER. Specify the subblocks in the input matrices A and B , whose GSVD is computed.

a,b,u,v,q,work REAL for stgsja
 DOUBLE PRECISION for dtgsja
 COMPLEX for ctgsja
 DOUBLE COMPLEX for ztgsja.

Arrays:
a(lda,)* contains the m -by- n matrix A .
 The second dimension of a must be at least $\max(1, n)$.
b(l db,)* contains the p -by- n matrix B .
 The second dimension of b must be at least $\max(1, n)$.
 If $jobu = 'U'$, $u(ldu,*)$ must contain a matrix U_1 (usually the orthogonal/unitary matrix returned by ?ggsvvp).
 The second dimension of u must be at least $\max(1, m)$.
 If $jobv = 'V'$, $v(ldv,*)$ must contain a matrix V_1 (usually the orthogonal/unitary matrix returned by ?ggsvvp).
 The second dimension of v must be at least $\max(1, p)$.

If $jobq = 'Q'$, $q(ldq,*)$ must contain a matrix Q_1 (usually the orthogonal/unitary matrix returned by ?ggsvp).
 The second dimension of q must be at least $\max(1, n)$.
 $work(*)$ is a workspace array.
 The dimension of $work$ must be at least $\max(1, 2n)$.

lda INTEGER. The first dimension of a ; at least $\max(1, m)$.

ldb INTEGER. The first dimension of b ; at least $\max(1, p)$.

ldu INTEGER. The first dimension of the array u .
 $ldu \geq \max(1, m)$ if $jobu = 'U'$; $ldu \geq 1$ otherwise.

ldv INTEGER. The first dimension of the array v .
 $ldv \geq \max(1, p)$ if $jobv = 'V'$; $ldv \geq 1$ otherwise.

ldq INTEGER. The first dimension of the array q .
 $ldq \geq \max(1, n)$ if $jobq = 'Q'$; $ldq \geq 1$ otherwise.

tola, tolb REAL for single-precision flavors
 DOUBLE PRECISION for double-precision flavors.
tola and *tolb* are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in ?ggsvp:
 $tola = \max(m, n) * |A| * \text{MACHEPS}$,
 $tolb = \max(p, n) * |B| * \text{MACHEPS}$.

Output Parameters

a On exit, $a(n-k+1:n, 1:\min(k+1, m))$ contains the triangular matrix R or part of R .

b On exit, if necessary, $b(m-k+1: l, n+m-k-l+1: n)$ contains a part of R .

alpha, beta REAL for single-precision flavors
 DOUBLE PRECISION for double-precision flavors.
 Arrays, DIMENSION at least $\max(1, n)$. Contain the generalized singular value pairs of A and B :
 $alpha(1:k) = 1$,
 $beta(1:k) = 0$,
 and if $m-k-l \geq 0$,
 $alpha(k+1:k+1) = \text{diag}(C)$,
 $beta(k+1:k+1) = \text{diag}(S)$,

or if $m-k-l < 0$,
 $alpha(k+1:m) = C$, $alpha(m+1:k+l) = 0$
 $beta(K+1:M) = S$,
 $beta(m+1:k+l) = 1$.
 Furthermore, if $k+l < n$,
 $alpha(k+l+1:n) = 0$ and
 $beta(k+l+1:n) = 0$.

u If *jobu* = 'I', *u* contains the orthogonal/unitary matrix *U*.
 If *jobu* = 'U', *u* contains the product $U_1 * U$.
 If *jobu* = 'N', *u* is not referenced.

v If *jobv* = 'I', *v* contains the orthogonal/unitary matrix *U*.
 If *jobv* = 'V', *v* contains the product $V_1 * V$.
 If *jobv* = 'N', *v* is not referenced.

q If *jobq* = 'I', *q* contains the orthogonal/unitary matrix *U*.
 If *jobq* = 'Q', *q* contains the product $Q_1 * Q$.
 If *jobq* = 'N', *q* is not referenced.

ncycle INTEGER. The number of cycles required for convergence.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = 1, the procedure does not converge after MAXIT cycles.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `tgsja` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m, n) .
<i>b</i>	Holds the matrix <i>B</i> of size (p, n) .
<i>u</i>	Holds the matrix <i>U</i> of size (m, m) .
<i>v</i>	Holds the matrix <i>V</i> of size (p, p) .
<i>q</i>	Holds the matrix <i>Q</i> of size (n, n) .
<i>alpha</i>	Holds the vector of length <i>n</i> .
<i>beta</i>	Holds the vector of length <i>n</i> .

<i>jobu</i>	<p>If omitted, this argument is restored based on the presence of argument <i>u</i> as follows: <i>jobu</i> = 'U', if <i>u</i> is present, <i>jobu</i> = 'N', if <i>u</i> is omitted. If present, <i>jobu</i> must be equal to 'I' or 'U' and the argument <i>u</i> must also be present. Note that there will be an error condition if <i>jobu</i> is present and <i>u</i> omitted.</p>
<i>jobv</i>	<p>If omitted, this argument is restored based on the presence of argument <i>v</i> as follows: <i>jobv</i> = 'V', if <i>v</i> is present, <i>jobv</i> = 'N', if <i>v</i> is omitted. If present, <i>jobv</i> must be equal to 'I' or 'V' and the argument <i>v</i> must also be present. Note that there will be an error condition if <i>jobv</i> is present and <i>v</i> omitted.</p>
<i>jobq</i>	<p>If omitted, this argument is restored based on the presence of argument <i>q</i> as follows: <i>jobq</i> = 'Q', if <i>q</i> is present, <i>jobq</i> = 'N', if <i>q</i> is omitted. If present, <i>jobq</i> must be equal to 'I' or 'Q' and the argument <i>q</i> must also be present. Note that there will be an error condition if <i>jobq</i> is present and <i>q</i> omitted.</p>

Driver Routines

Each of the LAPACK driver routines solves a complete problem. To arrive at the solution, driver routines typically call a sequence of appropriate [computational routines](#).

Driver routines are described in the following sections :

[Linear Least Squares \(LLS\) Problems](#)

[Generalized LLS Problems](#)

[Symmetric Eigenproblems](#)

[Nonsymmetric Eigenproblems](#)

[Singular Value Decomposition](#)

[Generalized Symmetric Definite Eigenproblems](#)

Generalized Nonsymmetric Eigenproblems

Linear Least Squares (LLS) Problems

This section describes LAPACK driver routines used for solving linear least squares problems. [Table 4-8](#) lists all such routines for FORTRAN 77 interface. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-8 Driver Routines for Solving LLS Problems

Routine Name	Operation performed
<code>?gels</code>	Uses QR or LQ factorization to solve a overdetermined or underdetermined linear system with full rank matrix.
<code>?gelsy</code>	Computes the minimum-norm solution to a linear least squares problem using a complete orthogonal factorization of A.
<code>?gelss</code>	Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A.
<code>?gelsd</code>	Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A and a divide and conquer method.

`?gels`

Uses QR or LQ factorization to solve a overdetermined or underdetermined linear system with full rank matrix.

Syntax

FORTRAN 77:

```
call sgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call dgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call cgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
call zgels(trans, m, n, nrhs, a, lda, b, ldb, work, lwork, info)
```

Fortran 95:

```
call gels(a, b [,trans] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine solves overdetermined or underdetermined real/ complex linear systems involving an m -by- n matrix A , or its transpose/ conjugate-transpose, using a QR or LQ factorization of A . It is assumed that A has full rank.

The following options are provided:

1. If $trans = 'N'$ and $m \geq n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

$$\text{minimize } \|b - A*x\|_2$$

2. If $trans = 'N'$ and $m < n$: find the minimum norm solution of an underdetermined system $A*X = B$.

3. If $trans = 'T'$ or $'C'$ and $m \geq n$: find the minimum norm solution of an undetermined system $A_H*X = B$.

4. If $trans = 'T'$ or $'C'$ and $m < n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

$$\text{minimize } \|b - A^H*x\|_2$$

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- nrh solution matrix X .

Input Parameters

<i>trans</i>	CHARACTER*1. Must be 'N', 'T', or 'C'. If $trans = 'N'$, the linear system involves matrix A ; If $trans = 'T'$, the linear system involves the transposed matrix A^T (for real flavors only); If $trans = 'C'$, the linear system involves the conjugate-transposed matrix A^H (for complex flavors only).
<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix A ($n \geq 0$).

<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in <i>B</i> ($nrhs \geq 0$).
<i>a, b, work</i>	REAL for <i>sgels</i> DOUBLE PRECISION for <i>dgels</i> COMPLEX for <i>cgels</i> DOUBLE COMPLEX for <i>zgels</i> . Arrays: <i>a(lda,*)</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b(l db,*)</i> contains the matrix <i>B</i> of right hand side vectors, stored columnwise; <i>B</i> is <i>m</i> -by- <i>nrhs</i> if <i>trans</i> = 'N' , or <i>n</i> -by- <i>nrhs</i> if <i>trans</i> = 'T' or 'C'. The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; must be at least $\max(1, m, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; must be at least $\min(m, n) + \max(1, m, n, nrhs)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	On exit, overwritten by the factorization data as follows: if $m \geq n$, array <i>a</i> contains the details of the <i>QR</i> factorization of the matrix <i>A</i> as returned by ?geqrf ; if $m < n$, array <i>a</i> contains the details of the <i>LQ</i> factorization of the matrix <i>A</i> as returned by ?gelqf .
<i>b</i>	If <i>info</i> = 0, <i>b</i> overwritten by the solution vectors, stored columnwise:

if $trans = 'N'$ and $m \geq n$, rows 1 to n of b contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements $n+1$ to m in that column; if $trans = 'N'$ and $m < n$, rows 1 to n of b contain the minimum norm solution vectors;

if $trans = 'T'$ or $'C'$ and $m \geq n$, rows 1 to m of b contain the minimum norm solution vectors; if $trans = 'T'$ or $'C'$ and $m < n$, rows 1 to m of b contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of modulus of elements $m+1$ to n in that column.

$work(1)$ If $info = 0$, on exit $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$info$ INTEGER.
 If $info = 0$, the execution is successful.
 If $info = -i$, the i -th parameter had an illegal value.
 If $info = i$, the i -th diagonal element of the triangular factor of A is zero, so that A does not have full rank; the least squares solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gels` interface are the following:

a	Holds the matrix A of size (m, n) .
b	Holds the matrix of size $\max(m, n)$ -by- $nrhs$. If $trans = 'N'$, then, on entry, the size of b is m -by- $nrhs$, If $trans = 'T'$, then, on entry, the size of b is n -by- $nrhs$,
$trans$	Must be $'N'$ or $'T'$. The default value is $'N'$.

Application Notes

For better performance, try using $lwork = \min(m, n) + \max(1, m, n, nrhs) * blocksize$, where $blocksize$ is a machine-dependent value (typically, 16 to 64) required for optimum performance of the *blocked algorithm*.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible $lwork$ sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gelsy

Computes the minimum-norm solution to a linear least squares problem using a complete orthogonal factorization of A.

Syntax

FORTRAN 77:

```
call sgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, info)
call dgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, info)
call cgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, rwork,
info)
call zgelsy(m, n, nrhs, a, lda, b, ldb, jpvt, rcond, rank, work, lwork, rwork,
info)
```

Fortran 95:

```
call gelsy(a, b [,rank] [,jpvt] [,rcond] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes the minimum-norm solution to a real/complex linear least squares problem:

$$\text{minimize } \|b - A*x\|_2$$

using a complete orthogonal factorization of A . A is an m -by- n matrix which may be rank-deficient. Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- $nrhs$ solution matrix X .

The routine first computes a QR factorization with column pivoting:

$$AP = Q \begin{pmatrix} R_{11} & R_{12} \\ \mathbf{0} & R_{22} \end{pmatrix}$$

with R_{11} defined as the largest leading submatrix whose estimated condition number is less than $1/rcond$. The order of R_{11} , $rank$, is the effective rank of A . Then, R_{22} is considered to be negligible, and R_{12} is annihilated by orthogonal/unitary transformations from the right, arriving at the complete orthogonal factorization:

$$AP = Q \begin{pmatrix} T_{11} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{pmatrix} Z$$

The minimum-norm solution is then

$$X = PZ^H \begin{pmatrix} T_{11}^{-1} & Q_1^H b \\ \mathbf{0} & \mathbf{0} \end{pmatrix}$$

where Q_1 consists of the first *rank* columns of Q . This routine is basically identical to the original `?gelsx` except three differences:

- The call to the subroutine `?geqpf` has been substituted by the call to the subroutine `?geqp3`. This subroutine is a BLAS-3 version of the QR factorization with column pivoting.
- Matrix B (the right hand side) is updated with BLAS-3.
- The permutation of matrix B (the right hand side) is faster and more simple.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix A ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).
<i>a, b, work</i>	REAL for <code>sgelsy</code> DOUBLE PRECISION for <code>dgelsy</code> COMPLEX for <code>cgelsy</code> DOUBLE COMPLEX for <code>zgelsy</code> . Arrays: <i>a</i> (<i>lda</i> ,*) contains the m -by- n matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb</i> ,*) contains the m -by- <i>nrhs</i> right hand side matrix B . The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; must be at least $\max(1, m, n)$.
<i>jpvt</i>	INTEGER. Array, DIMENSION at least $\max(1, n)$. On entry, if <i>jpvt</i> (<i>i</i>) $\neq 0$, the <i>i</i> -th column of A is permuted to the front of AP , otherwise the <i>i</i> -th column of A is a free column.
<i>rcond</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors.

	<i>rcond</i> is used to determine the effective rank of A , which is defined as the order of the largest leading triangular submatrix R_{11} in the QR factorization with pivoting of A , whose estimated condition number $< 1/rcond$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .
<i>rwork</i>	REAL for <i>cgelsy</i> DOUBLE PRECISION for <i>zgelsy</i> . Workspace array, DIMENSION at least $\max(1, 2n)$. Used in complex flavors only.

Output Parameters

<i>a</i>	On exit, overwritten by the details of the complete orthogonal factorization of A .
<i>b</i>	Overwritten by the n -by- <i>nrhs</i> solution matrix X .
<i>jpvt</i>	On exit, if <i>jpvt</i> (i) = k , then the i -th column of AP was the k -th column of A .
<i>rank</i>	INTEGER. The effective rank of A , that is, the order of the submatrix R_{11} . This is the same as the order of the submatrix T_{11} in the complete orthogonal factorization of A .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - i , the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *gelsy* interface are the following:

<i>a</i>	Holds the matrix A of size (m, n) .
----------	---

<i>b</i>	Holds the matrix of size $\max(m, n)$ -by- <i>nrhs</i> . On entry, contains the <i>m</i> -by- <i>nrhs</i> right hand side matrix <i>B</i> , On exit, overwritten by the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> .
<i>jpvt</i>	Holds the vector of length <i>n</i> . Default value for this element is <i>jpvt</i> (<i>i</i>) = 0.
<i>rcond</i>	Default value for this element is <i>rcond</i> = 100*EPSILON(1.0_WP).

Application Notes

For real flavors:

The unblocked strategy requires that:

$$lwork \geq \max(mn+3n+1, 2*mn + nrhs),$$

where $mn = \min(m, n)$.

The block algorithm requires that:

$$lwork \geq \max(mn+2n+nb*(n+1), 2*mn+nb*nrhs),$$

where *nb* is an upper bound on the blocksize returned by [ilaenv](#) for the routines `sgeqp3/dgeqp3`, `stzrzf/dtzrzf`, `stzrqf/dtzrqf`, `sormqr/dormqr`, and `sormrz/dormrz`.

For complex flavors:

The unblocked strategy requires that:

$$lwork \geq mn + \max(2*mn, n+1, mn + nrhs),$$

where $mn = \min(m, n)$.

The block algorithm requires that:

$$lwork < mn + \max(2*mn, nb*(n+1), mn+mn*nb, mn+ nb*nrhs),$$

where *nb* is an upper bound on the blocksize returned by [ilaenv](#) for the routines `cgeqp3/zgeqp3`, `ctzrzf/ztzrzf`, `ctzrqf/ztzrqf`, `cunmqr/zunmqr`, and `cunmrz/zunmrz`.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set `lwork = -1`, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`). This operation is called a workspace query.

Note that if you set `lwork` to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gelss

Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A .

Syntax

FORTRAN 77:

```
call sgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, info)
call dgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, info)
call cgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, rwork,
info)
call zgelss(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, rwork,
info)
```

Fortran 95:

```
call gelss(a, b [,rank] [,s] [,rcond] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes the minimum norm solution to a real linear least squares problem:

$$\text{minimize } \|b - A*x\|_2$$

using the singular value decomposition (SVD) of A . A is an m -by- n matrix which may be rank-deficient. Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- $nrhs$ solution matrix X . The effective rank of A is determined by treating as zero those singular values which are less than `rcond` times the largest singular value.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix <i>A</i> ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in <i>B</i> ($nrhs \geq 0$).
<i>a, b, work</i>	REAL for <i>sgelss</i> DOUBLE PRECISION for <i>dgelss</i> COMPLEX for <i>cgelss</i> DOUBLE COMPLEX for <i>zgelss</i> . Arrays: <i>a(lda,*)</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b(l db,*)</i> contains the <i>m</i> -by- <i>nrhs</i> right hand side matrix <i>B</i> . The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; must be at least $\max(1, m, n)$.
<i>rcond</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. <i>rcond</i> is used to determine the effective rank of <i>A</i> . Singular values $s(i) \leq rcond * s(1)$ are treated as zero. If <i>rcond</i> < 0, machine precision is used instead.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; $lwork \geq 1$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .
<i>rwork</i>	REAL for <i>cgelss</i> DOUBLE PRECISION for <i>zgelss</i> .

Workspace array used in complex flavors only. DIMENSION at least $\max(1, 5 * \min(m, n))$.

Output Parameters

<i>a</i>	On exit, the first $\min(m, n)$ rows of <i>A</i> are overwritten with its right singular vectors, stored row-wise.
<i>b</i>	Overwritten by the <i>n</i> -by- <i>nrhs</i> solution matrix <i>X</i> . If $m \geq n$ and <i>rank</i> = <i>n</i> , the residual sum-of-squares for the solution in the <i>i</i> -th column is given by the sum of squares of modulus of elements <i>n</i> +1: <i>m</i> in that column.
<i>s</i>	REAL for single precision flavors DOUBLE PRECISION for double precision flavors. Array, DIMENSION at least $\max(1, \min(m, n))$. The singular values of <i>A</i> in decreasing order. The condition number of <i>A</i> in the 2-norm is $k_2(A) = s(1) / s(\min(m, n))$.
<i>rank</i>	INTEGER. The effective rank of <i>A</i> , that is, the number of singular values which are greater than <i>rcond</i> * <i>s</i> (1).
<i>work</i> (1)	If <i>info</i> = 0, on exit, <i>work</i> (1) contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , then the algorithm for computing the SVD failed to converge; <i>i</i> indicates the number of off-diagonal elements of an intermediate bidiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gelss` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (m, n) .
----------	--

<i>b</i>	Holds the matrix of size $\max(m, n)$ -by- <i>nrhs</i> . On entry, contains the m -by- <i>nrhs</i> right hand side matrix <i>B</i> , On exit, overwritten by the n -by- <i>nrhs</i> solution matrix <i>X</i> .
<i>s</i>	Holds the vector of length $\min(m, n)$.
<i>rcond</i>	Default value for this element is $rcond = 100 * \text{EPSILON}(1.0_WP)$.

Application Notes

For real flavors:

$$lwork \geq 3 * \min(m, n) + \max(2 * \min(m, n), \max(m, n), nrhs)$$

For complex flavors:

$$lwork \geq 2 * \min(m, n) + \max(m, n, nrhs)$$

For good performance, *lwork* should generally be larger.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value ($work(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?gelsd

Computes the minimum-norm solution to a linear least squares problem using the singular value decomposition of A and a divide and conquer method.

Syntax

FORTRAN 77:

```
call sgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, iwork, info)
```

```
call dgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, iwork, info)
```

```
call cgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, rwork, iwork, info)
```

```
call zgelsd(m, n, nrhs, a, lda, b, ldb, s, rcond, rank, work, lwork, rwork, iwork, info)
```

Fortran 95:

```
call gelsd(a, b [,rank] [,s] [,rcond] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes the minimum-norm solution to a real linear least squares problem:

$$\text{minimize } \|b - A*x\|_2$$

using the singular value decomposition (SVD) of A . A is an m -by- n matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m -by- $nrhs$ right hand side matrix B and the n -by- $nrhs$ solution matrix X .

The problem is solved in three steps:

1. Reduce the coefficient matrix A to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS).

2. Solve the BLS using a divide and conquer approach.
3. Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than $rcond$ times the largest singular value.

The routine uses auxiliary routines `?lals0` and `?lalsa`.

Input Parameters

<i>m</i>	INTEGER. The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	INTEGER. The number of columns of the matrix A ($n \geq 0$).
<i>nrhs</i>	INTEGER. The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).
<i>a, b, work</i>	REAL for <code>sgelsd</code> DOUBLE PRECISION for <code>dgelsd</code> COMPLEX for <code>cgelsd</code> DOUBLE COMPLEX for <code>zgelsd</code> . Arrays: <i>a</i> (<i>lda</i> ,*) contains the m -by- n matrix A . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>b</i> (<i>ldb</i> ,*) contains the m -by- $nrhs$ right hand side matrix B . The second dimension of <i>b</i> must be at least $\max(1, nrhs)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, m)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; must be at least $\max(1, m, n)$.
<i>rcond</i>	REAL for single-precision flavors DOUBLE PRECISION for double-precision flavors. <i>rcond</i> is used to determine the effective rank of A . Singular values $s(i) \leq rcond * s(1)$ are treated as zero. If <i>rcond</i> ≤ 0 , machine precision is used instead.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; $lwork \geq 1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the array $work$ and the minimum sizes of the arrays $rwork$ and $iwork$, and returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ is issued by [xerbla](#).

See *Application Notes* for the suggested value of $lwork$.

$iwork$ INTEGER. Workspace array. See *Application Notes* for the suggested dimension of $iwork$.

$rwork$ REAL for `cgelsd`
DOUBLE PRECISION for `zgelsd`.
Workspace array, used in complex flavors only. See *Application Notes* for the suggested dimension of $rwork$.

Output Parameters

a On exit, A has been overwritten.

b Overwritten by the n -by- $nrhs$ solution matrix X .
If $m \geq n$ and $rank = n$, the residual sum-of-squares for the solution in the i -th column is given by the sum of squares of modulus of elements $n+1:m$ in that column.

s REAL for single precision flavors
DOUBLE PRECISION for double precision flavors.
Array, DIMENSION at least $\max(1, \min(m, n))$. The singular values of A in decreasing order. The condition number of A in the 2-norm is
 $k^2(A) = s(1) / s(\min(m, n))$.

$rank$ INTEGER. The effective rank of A , that is, the number of singular values which are greater than $rcond * s(1)$.

$work(1)$ If $info = 0$, on exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance. Use this $lwork$ for subsequent runs.

$rwork(1)$ If $info = 0$, on exit, $rwork(1)$ returns the minimum size of the workspace array $iwork$ required for optimum performance.

iwork(1) If *info* = 0, on exit, *iwork*(1) returns the minimum size of the workspace array *iwork* required for optimum performance.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, then the algorithm for computing the SVD failed to converge; *i* indicates the number of off-diagonal elements of an intermediate bidiagonal form that did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gelsd` interface are the following:

a Holds the matrix *A* of size (*m*,*n*).

b Holds the matrix of size max(*m*,*n*)-by-*nrhs*. On entry, contains the *m*-by-*nrhs* right hand side matrix *B*, On exit, overwritten by the *n*-by-*nrhs* solution matrix *X*.

s Holds the vector of length min(*m*,*n*).

rcond Default value for this element is *rcond* = 100*EPSILON(1.0_WP).

Application Notes

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

The exact minimum amount of workspace needed depends on *m*, *n* and *nrhs*. The size *lwork* of the workspace array *work* must be as given below.

For real flavors:

If $m \geq n$,

$$lwork \geq 12n + 2n*smlsiz + 8n*nlvl + n*nrhs + (smlsiz+1)^2;$$

If $m < n$,

$$lwork \geq 12m + 2m*smlsiz + 8m*nlvl + m*nrhs + (smlsiz+1)^2;$$

For complex flavors:

If $m \geq n$,

$$lwork < 2n + n*nrhs;$$

If $m < n$,

$$lwork \geq 2m + m*nrhs;$$

where *smlsiz* is returned by *ilaenv* and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and

$$nlvl = \text{INT}(\log_2(\min(m, n)/(smlsiz+1))) + 1.$$

For good performance, *lwork* should generally be larger.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The dimension of the workspace array *iwork* must be at least

$$3*\min(m, n)*nlvl + 11*\min(m, n).$$

The dimension of the workspace array *iwork* (for complex flavors) must be at least $\max(1, lrwork)$.

$$lrwork \geq 10n + 2n*smlsiz + 8n*nlvl + 3*smlsiz*nrhs + (smlsiz+1)^2 \text{ if } m \geq n, \text{ and}$$

$$lrwork \geq 10m + 2m*smlsiz + 8m*nlvl + 3*smlsiz*nrhs + (smlsiz+1)^2 \text{ if } m < n.$$

Generalized LLS Problems

This section describes LAPACK driver routines used for solving generalized linear least squares problems. [Table 4-9](#) lists all such routines for FORTRAN 77 interface. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-9 Driver Routines for Solving Generalized LLS Problems

Routine Name	Operation performed
?gglse	Solves the linear equality-constrained least squares problem using a generalized RQ factorization.
?ggglm	Solves a general Gauss-Markov linear model problem using a generalized QR factorization.

?gglse

Solves the linear equality-constrained least squares problem using a generalized RQ factorization.

Syntax

FORTRAN 77:

```
call sgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call dgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call cgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
call zgglse(m, n, p, a, lda, b, ldb, c, d, x, work, lwork, info)
```

Fortran 95:

```
call gglse(a, b, c, d, x [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine solves the linear equality-constrained least squares (LSE) problem:

minimize $\|c - A*x\|^2$ subject to $B*x = d$

where A is an m -by- n matrix, B is a p -by- n matrix, c is a given m -vector, and d is a given p -vector. It is assumed that $p \leq n \leq m+p$, and

$$\text{rank}(B) = p \text{ and } \text{rank} \begin{pmatrix} A \\ B \end{pmatrix} = n .$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a generalized RQ factorization of the matrices (B, A) given by

$$B = \begin{pmatrix} 0 & R \end{pmatrix} * Q, \quad A = Z * T * Q$$

Input Parameters

m	INTEGER. The number of rows of the matrix A ($m \geq 0$).
n	INTEGER. The number of columns of the matrices A and B ($n \geq 0$).
p	INTEGER. The number of rows of the matrix B ($0 \leq p \leq n \leq m+p$).
$a, b, c, d, work$	REAL for <code>sggls</code> DOUBLE PRECISION for <code>dggls</code> COMPLEX for <code>cggls</code> DOUBLE COMPLEX for <code>zggls</code> . Arrays: $a(lda,*)$ contains the m -by- n matrix A . The second dimension of a must be at least $\max(1, n)$. $b(l db,*)$ contains the p -by- n matrix B . The second dimension of b must be at least $\max(1, n)$. $c(*)$, dimension at least $\max(1, m)$, contains the right hand side vector for the least squares part of the LSE problem. $d(*)$, dimension at least $\max(1, p)$, contains the right hand side vector for the constrained equation. $work$ is a workspace array, its dimension $\max(1, lwork)$.
lda	INTEGER. The first dimension of a ; at least $\max(1, m)$.
ldb	INTEGER. The first dimension of b ; at least $\max(1, p)$.
$lwork$	INTEGER. The size of the $work$ array;

$lwork \geq \max(1, m+n+p)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by [xerbla](#). See *Application Notes* for the suggested value of *lwork*.

Output Parameters

<i>x</i>	REAL for sgglse DOUBLE PRECISION for dgglse COMPLEX for cgglse DOUBLE COMPLEX for zgglse. Array, DIMENSION at least $\max(1, n)$. On exit, contains the solution of the LSE problem.
<i>a</i>	On exit, the elements on and above the diagonal of the array contain the $\min(m, n)$ -by- n upper trapezoidal matrix <i>T</i> .
<i>b</i>	On exit, the upper triangle of the subarray $b(1:p, n-p+1:n)$ contains the p -by- p upper triangular matrix <i>R</i> .
<i>d</i>	On exit, <i>d</i> is destroyed.
<i>c</i>	On exit, the residual sum-of-squares for the solution is given by the sum of squares of elements $n-p+1$ to m of vector <i>c</i> .
<i>work(1)</i>	If <i>info</i> = 0, on exit, <i>work(1)</i> contains the minimum value of <i>lwork</i> required for optimum performance. Use this <i>lwork</i> for subsequent runs.
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = 1, the upper triangular factor <i>R</i> associated with <i>B</i> in the generalized RQ factorization of the pair (<i>B</i> , <i>A</i>) is singular, so that $\text{rank}(B) < P$; the least squares solution could not be computed. If <i>info</i> = 2, the $(n-p)$ -by- $(n-p)$ part of the upper trapezoidal factor <i>T</i> associated with <i>A</i> in the generalized RQ factorization of the pair (<i>B</i> , <i>A</i>) is singular, so that

$$\text{rank} \begin{pmatrix} A \\ B \end{pmatrix} < n$$

; the least squares solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `gglse` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>m</i> , <i>n</i>).
<i>b</i>	Holds the matrix <i>B</i> of size (<i>p</i> , <i>n</i>).
<i>c</i>	Holds the vector of length (<i>m</i>).
<i>d</i>	Holds the vector of length (<i>p</i>).
<i>x</i>	Holds the vector of length <i>n</i> .

Application Notes

For optimum performance, use

$$lwork \geq p + \min(m, n) + \max(m, n) * nb,$$

where *nb* is an upper bound for the optimal blocksizes for `?geqrf`, `?gerqf`, `?ormqr`/`?unmqr` and `?ormrq`/`?unmrq`.

You may set *lwork* to -1. The routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?ggglm

Solves a general Gauss-Markov linear model problem using a generalized QR factorization.

Syntax

FORTRAN 77:

```
call sggglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call dggglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call cggglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
call zggglm(n, m, p, a, lda, b, ldb, d, x, y, work, lwork, info)
```

Fortran 95:

```
call ggglm(a, b, d, x, y [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine solves a general Gauss-Markov linear model (GLM) problem:

$$\text{minimize}_x \|y\|_2 \text{ subject to } d = A*x + B*y$$

where A is an n -by- m matrix, B is an n -by- p matrix, and d is a given n -vector. It is assumed that $m \leq n \leq m+p$, and $\text{rank}(A) = m$ and $\text{rank}(A \ B) = n$.

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y , which is obtained using a generalized QR factorization of the matrices (A, B) given by

$$A = Q \begin{pmatrix} R \\ 0 \end{pmatrix}; \quad B = Q * T * Z.$$

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\text{minimize}_x \|B^{-1}(d-A*x)\|_2.$$

Input Parameters

<i>n</i>	INTEGER. The number of rows of the matrices <i>A</i> and <i>B</i> ($n \geq 0$).
<i>m</i>	INTEGER. The number of columns in <i>A</i> ($m \geq 0$).
<i>p</i>	INTEGER. The number of columns in <i>B</i> ($p \geq n - m$).
<i>a, b, d, work</i>	REAL for sggglm DOUBLE PRECISION for dggglm COMPLEX for cggglm DOUBLE COMPLEX for zggglm. Arrays: <i>a</i> (<i>lda</i> ,*) contains the <i>n</i> -by- <i>m</i> matrix <i>A</i> . The second dimension of <i>a</i> must be at least $\max(1, m)$. <i>b</i> (<i>ldb</i> ,*) contains the <i>n</i> -by- <i>p</i> matrix <i>B</i> . The second dimension of <i>b</i> must be at least $\max(1, p)$. <i>d</i> (*), dimension at least $\max(1, n)$, contains the left hand side of the GLM equation. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of <i>a</i> ; at least $\max(1, n)$.
<i>ldb</i>	INTEGER. The first dimension of <i>b</i> ; at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The size of the <i>work</i> array; $lwork \geq \max(1, n+m+p)$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by xerbla . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>x, y</i>	REAL for sggglm DOUBLE PRECISION for dggglm COMPLEX for cggglm DOUBLE COMPLEX for zggglm. Arrays <i>x</i> (*), <i>y</i> (*). DIMENSION at least $\max(1, m)$ for <i>x</i> and at least $\max(1, p)$ for <i>y</i> .
-------------	--

	On exit, x and y are the solutions of the GLM problem.
a	On exit, the upper triangular part of the array a contains the m -by- m upper triangular matrix R .
b	On exit, if $n \leq p$, the upper triangle of the subarray $b(1:n, p-n+1:p)$ contains the n -by- n upper triangular matrix T ; if $n > p$, the elements on and above the $(n-p)$ -th subdiagonal contain the n -by- p upper trapezoidal matrix T .
d	On exit, d is destroyed
$work(1)$	If $info = 0$, on exit, $work(1)$ contains the minimum value of $lwork$ required for optimum performance.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = 1$, the upper triangular factor R associated with A in the generalized QR factorization of the pair (A, B) is singular, so that $rank(A) < m$; the least squares solution could not be computed. If $info = 2$, the bottom $(n-m)$ -by- $(n-m)$ part of the upper trapezoidal factor T associated with B in the generalized QR factorization of the pair (A, B) is singular, so that $rank(A B) < n$; the least squares solution could not be computed.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `ggglm` interface are the following:

a	Holds the matrix A of size (n, m) .
b	Holds the matrix B of size (n, p) .
d	Holds the vector of length n .
x	Holds the vector of length (m) .
y	Holds the vector of length (p) .

Application Notes

For optimum performance, use

$$lwork \geq m + \min(n, p) + \max(n, p) * nb,$$

where nb is an upper bound for the optimal blocksizes for `?geqrf`, `?gerqf`, `?ormqr/?unmqr` and `?ormrq/?unmrq`.

You may set $lwork$ to -1. The routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$). This operation is called a workspace query.

Note that if you set $lwork$ to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Symmetric Eigenproblems

This section describes LAPACK driver routines used for solving symmetric eigenvalue problems. See also computational routines [computational routines](#) that can be called to solve these problems. [Table 4-10](#) lists all such driver routines for FORTRAN 77 interface. Respective routine names in Fortran 95 interface are without the first symbol (see [Routine Naming Conventions](#)).

Table 4-10 Driver Routines for Solving Symmetric Eigenproblems

Routine Name	Operation performed
<code>?syev/?heev</code>	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix.
<code>?syevd/?heevd</code>	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian matrix using divide and conquer algorithm.
<code>?syevx/?heevx</code>	Computes selected eigenvalues and, optionally, eigenvectors of a symmetric / Hermitian matrix.
<code>?syevr/?heevr</code>	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix using the Relatively Robust Representations.
<code>?spev/?hpev</code>	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix in packed storage.
<code>?spevd/?hpevd</code>	Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian matrix held in packed storage.

Routine Name	Operation performed
?spevx/?hpevx	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian matrix in packed storage.
?sbev /?hbev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian band matrix.
?sbevd/?hbevd	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric / Hermitian band matrix using divide and conquer algorithm.
?sbevz/?hbevz	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric / Hermitian band matrix.
?stev	Computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix.
?stevd	Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric tridiagonal matrix using divide and conquer algorithm.
?stevx	Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.
?stevr	Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix using the Relatively Robust Representations.

[?syev](#)

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyev(jobz, uplo, n, a, lda, w, work, lwork, info)
call dsyev(jobz, uplo, n, a, lda, w, work, lwork, info)
```

Fortran 95:

```
call syev(a, w [,jobz] [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A .

Note that for most cases of real symmetric eigenvalue problems the default choice should be `?syevr` function as its underlying algorithm is faster and uses less workspace.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>a, work</i>	REAL for <code>ssyev</code> DOUBLE PRECISION for <code>dsyev</code> Arrays: <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix A , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . Constraint: $lwork \geq \max(1, 3n-1)$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .

Output Parameters

<i>a</i>	On exit, if <i>jobz</i> = 'V', then if <i>info</i> = 0, array <i>a</i> contains the orthonormal eigenvectors of the matrix <i>A</i> . If <i>jobz</i> = 'N', then on exit the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>w</i>	REAL for <i>ssyev</i> DOUBLE PRECISION for <i>dsyev</i> Array, DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order.
<i>work</i> (1)	On exit, if <i>lwork</i> > 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *syev* interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length <i>n</i> .
<i>job</i>	Must be 'N' or 'V'. The default value is 'N'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For optimum performance set $lwork \geq (nb+2)*n$, where *nb* is the blocksize for *?sytrd* returned by *ilaenv*.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

If it is not clear how much workspace to supply, use a generous value of *lwork* for the first run, or set *lwork* = -1.

If *lwork* has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array on exit. Use this value (*work*(1)) for subsequent runs.

If *lwork* = -1, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array *work*. This operation is called a workspace query.

Note that if *lwork* is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

zheev

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call zheev(jobz, uplo, n, a, lda, w, work, lwork, rwork, info)
```

```
call zheev(jobz, uplo, n, a, lda, w, work, lwork, rwork, info)
```

Fortran 95:

```
call heev(a, w [,jobz] [,uplo] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A .

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be `?heevr` function as its underlying algorithm is faster and uses less workspace.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>a, work</i>	COMPLEX for <code>cheev</code> DOUBLE COMPLEX for <code>zheev</code> Arrays: <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix A , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . C onstraint: $lwork \geq \max(1, 2n-1)$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by `xerbla`. See *Application Notes* for the suggested value of $lwork$.

$work$ REAL for cheev
DOUBLE PRECISION for zheev.
Workspace array, DIMENSION at least $\max(1, 3n-2)$.

Output Parameters

a On exit, if $jobz = 'V'$, then if $info = 0$, array a contains the orthonormal eigenvectors of the matrix A .
If $jobz = 'N'$, then on exit the lower triangle (if $uplo = 'L'$) or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten.

w REAL for cheev
DOUBLE PRECISION for zheev
Array, DIMENSION at least $\max(1, n)$.
If $info = 0$, contains the eigenvalues of the matrix A in ascending order.

$work(1)$ On exit, if $lwork > 0$, then $work(1)$ returns the required minimal size of $lwork$.

$info$ INTEGER.
If $info = 0$, the execution is successful.
If $info = -i$, the i -th parameter had an illegal value.
If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `heev` interface are the following:

a Holds the matrix A of size (n, n) .
 w Holds the vector of length n .

job Must be 'N' or 'V'. The default value is 'N'.
uplo Must be 'U' or 'L'. The default value is 'U'.

Application Notes

For optimum performance use

$$lwork \geq (nb+1)*n,$$

where *nb* is the blocksize for `?hetrd` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of *lwork* for the first run or set *lwork* = -1.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work*(1)) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

?syevd

Computes all eigenvalues and (optionally) all eigenvectors of a real symmetric matrix using divide and conquer algorithm.

Syntax

FORTRAN 77:

```
call ssyevd(jobz, uplo, n, a, lda, w, work, lwork, iwork, liwork, info)
call dsyevd(jobz, uplo, n, a, lda, w, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call syevd(a, w [,jobz] [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix A . In other words, it can compute the spectral factorization of A as: $A = Z*\Lambda*Z^T$.

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A*z_i = \lambda_i*z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Note that for most cases of real symmetric eigenvalue problems the default choice should be `?syevr` function as its underlying algorithm is faster and uses less workspace. `?syevd` requires more workspace but is faster in some cases, especially for large matrices.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	REAL for <code>ssyevd</code> DOUBLE PRECISION for <code>dsyevd</code> Array, DIMENSION (<i>lda</i> , *). <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i> , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i> . Must be at least $\max(1, n)$.

work REAL for ssyevd
DOUBLE PRECISION for dsyevd.
Workspace array, DIMENSION at least *lwork*.

lwork INTEGER.
The dimension of the array *work*.
Constraints:
if $n \leq 1$, then $lwork \geq 1$;
if $jobz = 'N'$ and $n > 1$, then $lwork \geq 2*n + 1$;
if $jobz = 'V'$ and $n > 1$, then $lwork \geq 2*n^2 + 6*n + 1$.
If $lwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER.
Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.
The dimension of the array *iwork*.
Constraints:
if $n \leq 1$, then $liwork \geq 1$;
if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;
if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n + 3$.
If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w REAL for ssyevd
DOUBLE PRECISION for dsyevd
Array, DIMENSION at least $\max(1, n)$.

	If $info = 0$, contains the eigenvalues of the matrix A in ascending order. See also $info$.
a	If $jobz = 'V'$, then on exit this array is overwritten by the orthogonal matrix Z which contains the eigenvectors of A .
$work(1)$	On exit, if $lwork > 0$, then $work(1)$ returns the required minimal size of $lwork$.
$iwork(1)$	On exit, if $liwork > 0$, then $iwork(1)$ returns the required minimal size of $liwork$.
$info$	INTEGER. If $info = 0$, the execution is successful. If $info = i$, and $jobz = 'N'$, then the algorithm failed to converge; i indicates the number of off-diagonal elements of an intermediate tridiagonal form which did not converge to zero. If $info = i$, and $jobz = 'V'$, then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns $info/(n+1)$ through $\text{mod}(info, n+1)$. If $info = -i$, the i -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syevd` interface are the following:

a	Holds the matrix A of size (n, n) .
w	Holds the vector of length n .
$jobz$	Must be 'N' or 'V'. The default value is 'N'.
$uplo$	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If it is not clear how much workspace to supply, use a generous value of $lwork$ (or $liwork$) for the first run, or set $lwork = -1$ ($liwork = -1$).

If $lwork$ (or $liwork$) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$) on exit. Use this value ($work(1)$, $iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$). This operation is called a workspace query.

Note that if $lwork$ ($liwork$) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex analogue of this routine is [?heevd](#)

?heevd

Computes all eigenvalues and (optionally) all eigenvectors of a complex Hermitian matrix using divide and conquer algorithm.

Syntax

FORTRAN 77:

```
call cheevd(jobz, uplo, n, a, lda, w, work, lwork, rwork, lrwork, iwork,  
liwork, info)
```

```
call zheevd(jobz, uplo, n, a, lda, w, work, lwork, rwork, lrwork, iwork,  
liwork, info)
```

Fortran 95:

```
call heevd(a, w [,job] [,uplo] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix A . In other words, it can compute the spectral factorization of A as: $A = Z \Lambda Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be `?heevr` function as its underlying algorithm is faster and uses less workspace. `?heevd` requires more workspace but is faster in some cases, especially for large matrices.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	COMPLEX for <code>cheevd</code> DOUBLE COMPLEX for <code>zheevd</code> Array, DIMENSION (<i>lda</i> , *). <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i> , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>work</i>	COMPLEX for <code>cheevd</code> DOUBLE COMPLEX for <code>zheevd</code> . Workspace array, DIMENSION $\max(1, lwork)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . Constraints: if $n \leq 1$, then $lwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $lwork \geq n+1$;

if $jobz = 'V'$ and $n > 1$, then $lwork \geq n^2+2*n$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

$rwork$

REAL for cheevd

DOUBLE PRECISION for zheevd

Workspace array, DIMENSION at least $lrwork$.

$lrwork$

INTEGER.

The dimension of the array $rwork$. Constraints:

if $n \leq 1$, then $lrwork \geq 1$;

if $job = 'N'$ and $n > 1$, then $lrwork \geq n$;

if $job = 'V'$ and $n > 1$, then $lrwork \geq 2*n^2+ 5*n + 1$.

If $lrwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

$iwork$

INTEGER. Workspace array, its dimension $\max(1, liwork)$.

$liwork$

INTEGER.

The dimension of the array $iwork$. Constraints: if $n \leq 1$, then $liwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;

if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

<i>w</i>	REAL for cheevd DOUBLE PRECISION for zheevd Array, DIMENSION at least $\max(1, n)$. If <i>info</i> = 0, contains the eigenvalues of the matrix <i>A</i> in ascending order. See also <i>info</i> .
<i>a</i>	If <i>jobz</i> = 'V', then on exit this array is overwritten by the unitary matrix <i>Z</i> which contains the eigenvectors of <i>A</i> .
<i>work</i> (1)	On exit, if <i>lwork</i> > 0, then the real part of <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>rwork</i> (1)	On exit, if <i>lrwork</i> > 0, then <i>rwork</i> (1) returns the required minimal size of <i>lrwork</i> .
<i>iwork</i> (1)	On exit, if <i>liwork</i> > 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>i</i> , and <i>jobz</i> = 'N', then the algorithm failed to converge; <i>i</i> off-diagonal elements of an intermediate tridiagonal form did not converge to zero; if <i>info</i> = <i>i</i> , and <i>jobz</i> = 'V', then the algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns <i>info</i> /(<i>n</i> +1) through $\text{mod}(\text{info}, n+1)$. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `heevd` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length (<i>n</i>).
<i>jobz</i>	Must be 'N' or 'V'. The default value is 'N'.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $A + E$ such that $\|E\|_2 = O(\varepsilon) * \|A\|_2$, where ε is the machine precision.

If you are in doubt how much workspace to supply, use a generous value of *lwork* (*liwork* or *lrwork*) for the first run or set *lwork* = -1 (*liwork* = -1, *lrwork* = -1).

If you choose the first option and set any of admissible *lwork* (*liwork* or *lrwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*) on exit. Use this value (*work*(1), *iwork*(1), *rwork*(1)) for subsequent runs.

If you set *lwork* = -1 (*liwork* = -1, *lrwork* = -1), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *iwork*, *rwork*). This operation is called a workspace query.

Note that if you set *lwork* (*liwork*, *lrwork*) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real analogue of this routine is [?syevd](#). See also [?hpevd](#) for matrices held in packed storage, and [?hbevd](#) for banded matrices.

?syevx

Computes selected eigenvalues and, optionally, eigenvectors of a symmetric matrix.

Syntax

FORTRAN 77:

```
call ssyevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
           ldz, work, lwork, iwork, ifail, info)
```

```
call dsyevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
           ldz, work, lwork, iwork, ifail, info)
```

Fortran 95:

```
call syevx(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol]
           [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of real symmetric eigenvalue problems the default choice should be `?syeivr` function as its underlying algorithm is faster and uses less workspace. `?syevx` is faster for a few selected eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A', 'V', or 'I'. If <i>range</i> = 'A', all eigenvalues will be found. If <i>range</i> = 'V', all eigenvalues in the half-open interval $(v_l, v_u]$ will be found. If <i>range</i> = 'I', the eigenvalues with indices <i>i_l</i> through <i>i_u</i> will be found.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>a, work</i>	REAL for <code>ssyevx</code> DOUBLE PRECISION for <code>dsyevx</code> . Arrays: <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the symmetric matrix A , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i> . Must be at least $\max(1, n)$.

<i>vl, vu</i>	<p>REAL for <i>ssyevx</i> DOUBLE PRECISION for <i>dsyevx</i>. If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if <i>range</i> = 'A' or 'I'.</p>
<i>il, iu</i>	<p>INTEGER. If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: $1 \leq il \leq iu \leq n$, if $n > 0$; $il = 1$ and $iu = 0$, if $n = 0$. Not referenced if <i>range</i> = 'A' or 'V'.</p>
<i>abstol</i>	<p>REAL for <i>ssyevx</i> DOUBLE PRECISION for <i>dsyevx</i>. The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.</p>
<i>ldz</i>	<p>INTEGER. The first dimension of the output array <i>z</i>; $ldz \geq 1$. If <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.</p>
<i>lwork</i>	<p>INTEGER. The dimension of the array <i>work</i>. If $n \leq 1$ then $lwork \geq 1$, otherwise $lwork = 8 * n$. If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <i>xerbla</i>. See <i>Application Notes</i> for the suggested value of <i>lwork</i>.</p>
<i>iwork</i>	<p>INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.</p>

Output Parameters

<i>a</i>	<p>On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i>, including the diagonal, is overwritten.</p>
<i>m</i>	<p>INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu - il + 1$.</p>

w REAL for *ssyevx*
DOUBLE PRECISION for *dsyevx*
Array, DIMENSION at least $\max(1, n)$. The first m elements contain the selected eigenvalues of the matrix *A* in ascending order.

z REAL for *ssyevx*
DOUBLE PRECISION for *dsyevx*.
Array *z*(*ldz*,*) contains eigenvectors.
The second dimension of *z* must be at least $\max(1, m)$.
If *jobz* = 'V', then if *info* = 0, the first m columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with $w(i)$.
If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.
If *jobz* = 'N', then *z* is not referenced.
Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if *range* = 'V', the exact value of m is not known in advance and an upper bound must be used.

work(1) On exit, if *lwork* > 0, then *work*(1) returns the required minimal size of *lwork*.

ifail INTEGER.
Array, DIMENSION at least $\max(1, n)$.
If *jobz* = 'V', then if *info* = 0, the first m elements of *ifail* are zero; if *info* > 0, then *ifail* contains the indices of the eigenvectors that failed to converge.
If *jobz* = 'V', then *ifail* is not referenced.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.
If *info* = *i*, then *i* eigenvectors failed to converge; their indices are stored in the array *ifail*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syevx` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>w</code>	Holds the vector of length n .
<code>a</code>	Holds the matrix A of size (m, n) .
<code>ifail</code>	Holds the vector of length n .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>v1</code>	Default value for this element is $v1 = -\text{HUGE}(v1)$.
<code>vu</code>	Default value for this element is $vu = \text{HUGE}(v1)$.
<code>il</code>	Default value for this argument is $il = 1$.
<code>iu</code>	Default value for this argument is $iu = n$.
<code>abstol</code>	Default value for this element is $abstol = 0.0_WP$.
<code>jobz</code>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted. Note that there will be an error condition if <code>ifail</code> is present and z is omitted.
<code>range</code>	Restored based on the presence of arguments $v1, vu, il, iu$ as follows: $range = 'V'$, if one of or both $v1$ and vu are present, $range = 'I'$, if one of or both il and iu are present, $range = 'A'$, if none of $v1, vu, il, iu$ is present. Note that there will be an error condition if one of or both $v1$ and vu are present and at the same time one of or both il and iu are present.

Application Notes

For optimum performance use $lwork \geq (nb+3)*n$, where nb is the maximum of the blocksize for `?sytrd` and `?ormtr` returned by `ilaenv`.

If it is not clear how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If $lwork$ has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array $work$ on exit. Use this value ($work(1)$) for subsequent runs.

If $lwork = -1$, then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array $work$. This operation is called a workspace query.

Note that if $lwork$ is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon * |T|$ is used as tolerance, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues are computed most accurately when $abstol$ is set to twice the underflow threshold $2 * slamch('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2 * slamch('S')$.

zheevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix.

Syntax

FORTRAN 77:

```
call zheevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
           ldz, work, lwork, rwork, iwork, ifail, info)
```

```
call zheevx(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
           ldz, work, lwork, rwork, iwork, ifail, info)
```

Fortran 95:

```
call zheevx(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol]
           [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Note that for most cases of complex Hermitian eigenvalue problems the default choice should be `?heevr` function as its underlying algorithm is faster and uses less workspace. `?heevx` is faster for a few selected eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A', 'V', or 'I'. If <i>range</i> = 'A', all eigenvalues will be found. If <i>range</i> = 'V', all eigenvalues in the half-open interval (<i>v1</i> , <i>vu</i>] will be found. If <i>range</i> = 'I', the eigenvalues with indices <i>i1</i> through <i>iu</i> will be found.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of A . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>a, work</i>	COMPLEX for <code>cheevx</code> DOUBLE COMPLEX for <code>zheevx</code> . Arrays: <i>a</i> (<i>lda</i> ,*) is an array containing either upper or lower triangular part of the Hermitian matrix A , as specified by <i>uplo</i> . The second dimension of <i>a</i> must be at least $\max(1, n)$. <i>work</i> is a workspace array, its dimension $\max(1, lwork)$.
<i>lda</i>	INTEGER. The first dimension of the array <i>a</i> . Must be at least $\max(1, n)$.

<i>vl, vu</i>	REAL for <code>cheevx</code> DOUBLE PRECISION for <code>zheevx</code> . If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if <i>range</i> = 'A' or 'I'.
<i>il, iu</i>	INTEGER. If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: $1 \leq il \leq iu \leq n$, if $n > 0$; $il = 1$ and $iu = 0$, if $n = 0$. Not referenced if <i>range</i> = 'A' or 'V'.
<i>abstol</i>	REAL for <code>cheevx</code> DOUBLE PRECISION for <code>zheevx</code> . The absolute error tolerance for the eigenvalues. See <i>Application Notes</i> for more information.
<i>ldz</i>	INTEGER. The first dimension of the output array <i>z</i> ; $ldz \geq 1$. If <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.
<i>lwork</i>	INTEGER. The dimension of the array <i>work</i> . $lwork \geq 1$ if $n \leq 1$; otherwise at least $2*n$. If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by <code>xerbla</code> . See <i>Application Notes</i> for the suggested value of <i>lwork</i> .
<i>rwork</i>	REAL for <code>cheevx</code> DOUBLE PRECISION for <code>zheevx</code> . Workspace array, DIMENSION at least $\max(1, 7n)$.
<i>iwork</i>	INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
----------	---

m INTEGER. The total number of eigenvalues found; $0 \leq m \leq n$.
 If *range* = 'A', $m = n$, and if *range* = 'I', $m = iu-il+1$.

w REAL for cheevx
 DOUBLE PRECISION for zheevx
 Array, DIMENSION at least $\max(1, n)$. The first *m* elements contain the selected eigenvalues of the matrix *A* in ascending order.

z COMPLEX for cheevx
 DOUBLE COMPLEX for zheevx.
 Array *z*(*ldz*,*) contains eigenvectors.
 The second dimension of *z* must be at least $\max(1, m)$.
 If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).
 If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.
 If *jobz* = 'N', then *z* is not referenced. Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and an upper bound must be used.

work(1) On exit, if *lwork* > 0, then *work*(1) returns the required minimal size of *lwork*.

ifail INTEGER.
 Array, DIMENSION at least $\max(1, n)$.
 If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, then *ifail* contains the indices of the eigenvectors that failed to converge.
 If *jobz* = 'V', then *ifail* is not referenced.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, then *i* eigenvectors failed to converge; their indices are stored in the array *ifail*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `heevx` interface are the following:

<code>a</code>	Holds the matrix A of size (n, n) .
<code>w</code>	Holds the vector of length n .
<code>z</code>	Holds the matrix Z of size (n, n) .
<code>ifail</code>	Holds the vector of length n .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>v1</code>	Default value for this element is $v1 = -\text{HUGE}(v1)$.
<code>vu</code>	Default value for this element is $vu = \text{HUGE}(v1)$.
<code>il</code>	Default value for this argument is $il = 1$.
<code>iu</code>	Default value for this argument is $iu = n$.
<code>abstol</code>	Default value for this element is $abstol = 0.0_WP$.
<code>jobz</code>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted. Note that there will be an error condition if $ifail$ is present and z is omitted.
<code>range</code>	Restored based on the presence of arguments $v1, vu, il, iu$ as follows: $range = 'V'$, if one of or both $v1$ and vu are present, $range = 'I'$, if one of or both il and iu are present, $range = 'A'$, if none of $v1, vu, il, iu$ is present. Note that there will be an error condition if one of or both $v1$ and vu are present and at the same time one of or both il and iu are present.

Application Notes

For optimum performance use $lwork \geq (nb+1)*n$, where nb is the maximum of the blocksize for `?hetrd` and `?unmtr` returned by `ilaenv`.

If you are in doubt how much workspace to supply, use a generous value of $lwork$ for the first run or set $lwork = -1$.

If you choose the first option and set any of admissible *lwork* sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array *work* on exit. Use this value (*work(1)*) for subsequent runs.

If you set *lwork* = -1, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*). This operation is called a workspace query.

Note that if you set *lwork* to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * slamch('S')$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * slamch('S')$.

?syevr

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix using the Relatively Robust Representations.

Syntax

FORTRAN 77:

```
call ssyevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
ldz, isuppz, work, lwork, iwork, liwork, info)
```

```
call dsyevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,
ldz, isuppz, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call syevr(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol]
[,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix A to tridiagonal form T with a call to `?sytrd`. Then, whenever possible, `?syevr` calls `?stemr` to compute the eigenspectrum using Relatively Robust Representations. `?stemr` computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various "good" L^*D*L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the each unreduced block of T :

- a.** Compute $T - \sigma I = L^*D*L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of D and L cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- b.** Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).
- c.** For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- d.** For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter `abstol`.

The routine `?syevr` calls `?stemr` when the full spectrum is requested on machines that conform to the IEEE-754 floating point standard. `?syevr` calls `?stebz` and `?stein` on non-IEEE machines and when partial spectrum requests are made.

Note that `?syevr` is preferable for most cases of real symmetric eigenvalue problems as its underlying algorithm is fast and uses less workspace.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval:</p> $vl < \lambda(i) \leq vu.$ <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p> <p>For <i>range</i> = 'V' or 'I' and $iu-il < n-1$, <i>sstebz/dstebz</i> and <i>sstein/dstein</i> are called.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i>.</p> <p>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).</p>
<i>a, work</i>	<p>REAL for <i>ssyevr</i></p> <p>DOUBLE PRECISION for <i>dsyevr</i>.</p> <p>Arrays:</p> <p><i>a(lda,*)</i> is an array containing either upper or lower triangular part of the symmetric matrix <i>A</i>, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	<p>INTEGER. The first dimension of the array <i>a</i>. Must be at least $\max(1, n)$.</p>
<i>vl, vu</i>	<p>REAL for <i>ssyevr</i></p> <p>DOUBLE PRECISION for <i>dsyevr</i>.</p> <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $vl < vu$.</p> <p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p>
<i>il, iu</i>	<p>INTEGER.</p>

If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
 Constraint:
 $1 \leq il \leq iu \leq n$, if $n > 0$;
 $il=1$ and $iu=0$, if $n = 0$.
 If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol REAL for *ssyevr*
 DOUBLE PRECISION for *dsyevr*. The absolute error tolerance to which each eigenvalue/eigenvector is required.
 If *jobz* = 'V', the eigenvalues and eigenvectors output have residual norms bounded by *abstol*, and the dot products between different eigenvectors are bounded by *abstol*.
 If $abstol < n * \text{eps} * |T|$, then $n * \text{eps} * |T|$ is used instead, where *eps* is the machine precision, and $|T|$ is the 1-norm of the matrix *T*. The eigenvalues are computed to an accuracy of $\text{eps} * |T|$ irrespective of *abstol*.
 If high relative accuracy is important, set *abstol* to `?lamch('S')`.

ldz INTEGER. The leading dimension of the output array *z*.
 Constraints:
 $ldz \geq 1$ and
 $ldz \geq \max(1, n)$ if *jobz* = 'V'.

lwork INTEGER.
 The dimension of the array *work*.
 Constraint: $lwork \geq \max(1, 26n)$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work* array, returns this value as the first entry of the *work* array, and no error message related to *lwork* is issued by `xerbla`.
 See *Application Notes* for the suggested value of *lwork*.

iwork INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.
 The dimension of the array *iwork*, $lwork \geq \max(1, 10n)$.

If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued by [xerbla](#).

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L') or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>m</i>	INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$. If <i>range</i> = 'A', <i>m</i> = <i>n</i> , and if <i>range</i> = 'I', <i>m</i> = <i>iu-il</i> +1.
<i>w</i> , <i>z</i>	REAL for <i>ssyevr</i> DOUBLE PRECISION for <i>dsyevr</i> . Arrays: <i>w</i> (*), DIMENSION at least $\max(1, n)$, contains the selected eigenvalues in ascending order, stored in <i>w</i> (1) to <i>w</i> (<i>m</i>); <i>z</i> (<i>ldz</i> , *), the second dimension of <i>z</i> must be at least $\max(1, m)$. If <i>jobz</i> = 'V', then if <i>info</i> = 0, the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix <i>T</i> corresponding to the selected eigenvalues, with the <i>i</i> -th column of <i>z</i> holding the eigenvector associated with <i>w</i> (<i>i</i>). If <i>jobz</i> = 'N', then <i>z</i> is not referenced. Note that you must ensure that at least $\max(1, m)$ columns are supplied in the array <i>z</i> ; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and an upper bound must be used.
<i>isuppz</i>	INTEGER. Array, DIMENSION at least $2 * \max(1, m)$. The support of the eigenvectors in <i>z</i> , i.e., the indices indicating the nonzero elements in <i>z</i> . The <i>i</i> -th eigenvector is nonzero only in elements <i>isuppz</i> (2 <i>i</i> -1) through <i>isuppz</i> (2 <i>i</i>). Referenced only if eigenvectors are needed (<i>jobz</i> = 'V') and all eigenvalues are needed, that is, <i>range</i> = 'A' or <i>range</i> = 'I' and <i>il</i> = 1 and <i>iu</i> = <i>n</i> .
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .

<i>iwork(1)</i>	On exit, if <i>info</i> = 0, then <i>iwork(1)</i> returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , an internal error has occurred.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `syevr` interface are the following:

<i>a</i>	Holds the matrix <i>A</i> of size (<i>n</i> , <i>n</i>).
<i>w</i>	Holds the vector of length <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (<i>n</i> , <i>n</i>), where the values <i>n</i> and <i>m</i> are significant.
<i>isuppz</i>	Holds the vector of length ($2*m$), where the values ($2*m$) are significant.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>v1</i>	Default value for this element is $v1 = -HUGE(v1)$.
<i>vu</i>	Default value for this element is $vu = HUGE(v1)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if <i>isuppz</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>v1</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>v1</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>v1</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>v1</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

For optimum performance use $lwork \geq (nb+6)*n$, where nb is the maximum of the blocksize for `?sytrd` and `?ormtr` returned by `ilaenv`.

If it is not clear how much workspace to supply, use a generous value of $lwork$ (or $liwork$) for the first run or set $lwork = -1$ ($liwork = -1$).

If $lwork$ (or $liwork$) has any of admissible sizes, which is no less than the minimal value described, then the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$) on exit. Use this value ($work(1)$, $iwork(1)$) for subsequent runs.

If $lwork = -1$ ($liwork = -1$), then the routine returns immediately and provides the recommended workspace in the first element of the corresponding array ($work$, $iwork$). This operation is called a workspace query.

Note that if $lwork$ ($liwork$) is less than the minimal required value and is not equal to -1, then the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Normal execution of `?stegr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

?heevr

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix using the Relatively Robust Representations.

Syntax

FORTRAN 77:

```
call cheevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,  
ldz, isuppz, work, lwork, rwork, lrwork, iwork, liwork, info)
```

```
call zheevr(jobz, range, uplo, n, a, lda, vl, vu, il, iu, abstol, m, w, z,  
ldz, isuppz, work, lwork, rwork, lrwork, iwork, liwork, info)
```

Fortran 95:

```
call heevr(a, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,isuppz] [,abstol]
[,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A . Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

The routine first reduces the matrix A to tridiagonal form T with a call to `?hetrd`. Then, whenever possible, `?heevr` calls `?stegr` to compute the eigenspectrum using Relatively Robust Representations. `?stegr` computes eigenvalues by the *dqds* algorithm, while orthogonal eigenvectors are computed from various "good" $L^*D^*L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For each unreduced block (submatrix) of T :

- a.** Compute $T - \sigma I = L^*D^*L^T$, so that L and D define all the wanted eigenvalues to high relative accuracy. This means that small relative changes in the entries of D and L cause only small relative changes in the eigenvalues and eigenvectors. The standard (unfactored) representation of the tridiagonal matrix T does not have this property in general.
- b.** Compute the eigenvalues to suitable accuracy. If the eigenvectors are desired, the algorithm attains full accuracy of the computed eigenvalues only right before the corresponding vectors have to be computed, see Steps c) and d).
- c.** For each cluster of close eigenvalues, select a new shift close to the cluster, find a new factorization, and refine the shifted eigenvalues to suitable accuracy.
- d.** For each eigenvalue with a large enough relative separation, compute the corresponding eigenvector by forming a rank revealing twisted factorization. Go back to Step c) for any clusters that remain.

The desired accuracy of the output can be specified by the input parameter `abstol`.

The routine `?heevr` calls `?stemr` when the full spectrum is requested on machines which conform to the IEEE-754 floating point standard, or `?stebz` and `?stein` on non-IEEE machines and when partial spectrum requests are made.

Note that the routine `?heevr` is preferable for most cases of complex Hermitian eigenvalue problems as its underlying algorithm is fast and uses less workspace.

Input Parameters

<i>jobz</i>	<p>CHARACTER*1. Must be 'N' or 'V'.</p> <p>If <i>jobz</i> = 'N', then only eigenvalues are computed.</p> <p>If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.</p>
<i>range</i>	<p>CHARACTER*1. Must be 'A' or 'V' or 'I'.</p> <p>If <i>range</i> = 'A', the routine computes all eigenvalues.</p> <p>If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $v_l < \lambda(i) \leq v_u$.</p> <p>If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i>.</p> <p>For <i>range</i> = 'V' or 'I', <code>sstebz/dstebz</code> and <code>cstein/zstein</code> are called.</p>
<i>uplo</i>	<p>CHARACTER*1. Must be 'U' or 'L'.</p> <p>If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i>.</p> <p>If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i>.</p>
<i>n</i>	<p>INTEGER. The order of the matrix <i>A</i> ($n \geq 0$).</p>
<i>a, work</i>	<p>COMPLEX for <code>cheevr</code></p> <p>DOUBLE COMPLEX for <code>zheevr</code>.</p> <p>Arrays:</p> <p><i>a</i>(<i>lda</i>,*) is an array containing either upper or lower triangular part of the Hermitian matrix <i>A</i>, as specified by <i>uplo</i>.</p> <p>The second dimension of <i>a</i> must be at least $\max(1, n)$.</p> <p><i>work</i> is a workspace array, its dimension $\max(1, lwork)$.</p>
<i>lda</i>	<p>INTEGER. The first dimension of the array <i>a</i>.</p> <p>Must be at least $\max(1, n)$.</p>
<i>v_l, v_u</i>	<p>REAL for <code>cheevr</code></p> <p>DOUBLE PRECISION for <code>zheevr</code>.</p> <p>If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.</p> <p>Constraint: $v_l < v_u$.</p>

<i>il, iu</i>	<p>If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.</p> <p>INTEGER.</p> <p>If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.</p> <p>Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.</p> <p>If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.</p>
<i>abstol</i>	<p>REAL for <i>cheevr</i></p> <p>DOUBLE PRECISION for <i>zheevr</i>.</p> <p>The absolute error tolerance to which each eigenvalue/eigenvector is required.</p> <p>If <i>jobz</i> = 'V', the eigenvalues and eigenvectors output have residual norms bounded by <i>abstol</i>, and the dot products between different eigenvectors are bounded by <i>abstol</i>.</p> <p>If $abstol < n * eps * T$, then $n * eps * T$ will be used in its place, where <i>eps</i> is the machine precision, and T is the 1-norm of the matrix <i>T</i>. The eigenvalues are computed to an accuracy of $eps * T$ irrespective of <i>abstol</i>.</p> <p>If high relative accuracy is important, set <i>abstol</i> to <code>?lamch('S')</code>.</p>
<i>ldz</i>	<p>INTEGER. The leading dimension of the output array <i>z</i>.</p> <p>Constraints:</p> <p>$ldz \geq 1$ if <i>jobz</i> = 'N';</p> <p>$ldz \geq \max(1, n)$ if <i>jobz</i> = 'V'.</p>
<i>lwork</i>	<p>INTEGER.</p> <p>The dimension of the array <i>work</i>.</p> <p>Constraint: $lwork \geq \max(1, 2n)$.</p> <p>If <i>lwork</i> = -1, then a workspace query is assumed; the routine only calculates the optimal size of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, returns these values as the first entries of the <i>work</i>, <i>rwork</i> and <i>iwork</i> arrays, and no error message related to <i>lwork</i> or <i>lrwork</i> or <i>liwork</i> is issued by xerbla. See <i>Application Notes</i> for the suggested value of <i>lwork</i>.</p>
<i>rwork</i>	<p>REAL for <i>cheevr</i></p> <p>DOUBLE PRECISION for <i>zheevr</i>.</p>

lwork Workspace array, DIMENSION $\max(1, lwork)$.
 INTEGER.
 The dimension of the array *rwork*;
 $lwork \geq \max(1, 24n)$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#).

iwork INTEGER. Workspace array, its dimension $\max(1, liwork)$.
liwork INTEGER.
 The dimension of the array *iwork*,
 $lwork \geq \max(1, 10n)$.
 If *liwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#).

Output Parameters

a On exit, the lower triangle (if *uplo* = 'L') or the upper triangle (if *uplo* = 'U') of *A*, including the diagonal, is overwritten.

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$.
 If *range* = 'A', $m = n$, and if *range* = 'I', $m = iu-il+1$.

w REAL for *cheevr*
 DOUBLE PRECISION for *zheevr*.
 Array, DIMENSION at least $\max(1, n)$, contains the selected eigenvalues in ascending order, stored in *w*(1) to *w*(*m*).

z COMPLEX for *cheevr*
 DOUBLE COMPLEX for *zheevr*.
 Array *z*(*ldz*, *); the second dimension of *z* must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$. If $jobz = 'N'$, then z is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

<i>isuppz</i>	INTEGER. Array, DIMENSION at least $2 * \max(1, m)$. The support of the eigenvectors in z , i.e., the indices indicating the nonzero elements in z . The i -th eigenvector is nonzero only in elements $isuppz(2i-1)$ through $isuppz(2i)$. Referenced only if eigenvectors are needed ($jobz = 'V'$) and all eigenvalues are needed, that is, $range = 'A'$ or $range = 'I'$ and $il = 1$ and $iu = n$.
<i>work(1)</i>	On exit, if $info = 0$, then <i>work(1)</i> returns the required minimal size of <i>lwork</i> .
<i>rwork(1)</i>	On exit, if $info = 0$, then <i>rwork(1)</i> returns the required minimal size of <i>lrwork</i> .
<i>iwork(1)</i>	On exit, if $info = 0$, then <i>iwork(1)</i> returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If $info = 0$, the execution is successful. If $info = -i$, the i -th parameter had an illegal value. If $info = i$, an internal error has occurred.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `heevr` interface are the following:

<i>a</i>	Holds the matrix A of size (n, n) .
<i>w</i>	Holds the vector of length n .

<i>z</i>	Holds the matrix <i>z</i> of size (n, n) , where the values <i>n</i> and <i>m</i> are significant.
<i>isuppz</i>	Holds the vector of length $(2*n)$, where the values $(2*m)$ are significant.
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>vl</i>	Default value for this element is $vl = -HUGE(vl)$.
<i>vu</i>	Default value for this element is $vu = HUGE(vl)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted Note that there will be an error condition if <i>isuppz</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: <i>range</i> = 'V', if one of or both <i>vl</i> and <i>vu</i> are present, <i>range</i> = 'I', if one of or both <i>il</i> and <i>iu</i> are present, <i>range</i> = 'A', if none of <i>vl</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>vl</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

For optimum performance use $lwork \geq (nb+1)*n$, where *nb* is the maximum of the blocksize for ?hetrd and ?unmtr returned by [ilaenv](#).

If you are in doubt how much workspace to supply, use a generous value of *lwork* (or *lrwork*, or *liwork*) for the first run or set $lwork = -1$ ($lrwork = -1$, $liwork = -1$).

If you choose the first option and set any of admissible *lwork* (or *lrwork*, *liwork*) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (*work*, *rwork*, *iwork*) on exit. Use this value ($work(1)$, $rwork(1)$, $iwork(1)$) for subsequent runs.

If you set $lwork = -1$, the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (*work*, *rwork*, *iwork*). This operation is called a workspace query.

Note that if you set $lwork$ ($lrwork, liwork$) to less than the minimal required value and not -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

Normal execution of `?stegr` may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the IEEE standard default manner.

?spev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix in packed storage.

Syntax

FORTRAN 77:

```
call sspev(jobz, uplo, n, ap, w, z, ldz, work, info)
```

```
call dspev(jobz, uplo, n, ap, w, z, ldz, work, info)
```

Fortran 95:

```
call spev(ap, w [,uplo] [,z] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A .

If *uplo* = 'L', *ap* stores the packed lower triangular part of *A*.

n INTEGER. The order of the matrix *A* ($n \geq 0$).

ap, work REAL for *sspev*
DOUBLE PRECISION for *dspev*
Arrays:
ap(*) contains the packed upper or lower triangle of symmetric matrix *A*, as specified by *uplo*.
The dimension of *ap* must be at least $\max(1, n*(n+1)/2)$.

work (*) is a workspace array, DIMENSION at least $\max(1, 3n)$.

ldz INTEGER. The leading dimension of the output array *z*.
Constraints:
if *jobz* = 'N', then $ldz \geq 1$;
if *jobz* = 'V', then $ldz \geq \max(1, n)$.

Output Parameters

w, z REAL for *sspev*
DOUBLE PRECISION for *dspev*
Arrays:
w(*), DIMENSION at least $\max(1, n)$.
If *info* = 0, *w* contains the eigenvalues of the matrix *A* in ascending order.
z(*ldz*, *). The second dimension of *z* must be at least $\max(1, n)$.
If *jobz* = 'V', then if *info* = 0, *z* contains the orthonormal eigenvectors of the matrix *A*, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).
If *jobz* = 'N', then *z* is not referenced.

ap On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of *A*.

info INTEGER.
If *info* = 0, the execution is successful.
If *info* = -*i*, the *i*-th parameter had an illegal value.

If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spev` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>w</code>	Holds the vector with the number of elements n .
<code>z</code>	Holds the matrix Z of size (n, n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>jobz</code>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

?hpev

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.

Syntax

FORTRAN 77:

```
call chpev(jobz, uplo, n, ap, w, z, ldz, work, rwork, info)
call zhpev(jobz, uplo, n, ap, w, z, ldz, work, rwork, info)
```

Fortran 95:

```
call hpev(ap, w [,uplo] [,z] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage.

<i>jobz</i>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

?spevd

Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a real symmetric matrix held in packed storage.

Syntax

FORTRAN 77:

```
call sspevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, iwork, liwork, info)
call dspevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, iwork, liwork, info)
```

Fortran 95:

```
call spevd(ap, w [,uplo] [,z] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric matrix A (held in packed storage). In other words, it can compute the spectral factorization of A as:

$$A = Z \Lambda Z^T.$$

Here Λ is a diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the orthogonal matrix whose columns are the eigenvectors z_i . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

<code>jobz</code>	CHARACTER*1. Must be 'N' or 'V'. If <code>jobz = 'N'</code> , then only eigenvalues are computed. If <code>jobz = 'V'</code> , then eigenvalues and eigenvectors are computed.
<code>uplo</code>	CHARACTER*1. Must be 'U' or 'L'.

If *uplo* = 'U', *ap* stores the packed upper triangular part of *A*.
 If *uplo* = 'L', *ap* stores the packed lower triangular part of *A*.

n INTEGER. The order of the matrix *A* ($n \geq 0$).

ap, work REAL for *sspevd*
 DOUBLE PRECISION for *dspevd*
 Arrays:
ap(*) contains the packed upper or lower triangle of symmetric matrix *A*, as specified by *uplo*.
 The dimension of *ap* must be at least $\max(1, n*(n+1)/2)$
work is a workspace array, its dimension $\max(1, lwork)$.

ldz INTEGER. The leading dimension of the output array *z*.
 Constraints:
 if *jobz* = 'N', then $ldz \geq 1$;
 if *jobz* = 'V', then $ldz \geq \max(1, n)$.

lwork INTEGER.
 The dimension of the array *work*.
 Constraints:
 if $n \leq 1$, then $lwork \geq 1$;
 if *jobz* = 'N' and $n > 1$, then $lwork \geq 2*n$;
 if *jobz* = 'V' and $n > 1$, then
 $lwork \geq n^2 + 6*n + 1$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the required sizes of the *work* and *iwork* arrays, returns these values as the first entries of the *work* and *iwork* arrays, and no error message related to *lwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

iwork INTEGER. Workspace array, its dimension $\max(1, liwork)$.

liwork INTEGER.
 The dimension of the array *iwork*.
 Constraints:
 if $n \leq 1$, then $liwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;
 if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.
 If $liwork = -1$, then a workspace query is assumed; the routine only calculates the required sizes of the $work$ and $iwork$ arrays, returns these values as the first entries of the $work$ and $iwork$ arrays, and no error message related to $lwork$ or $liwork$ is issued by [xerbla](#). See *Application Notes* for details.

Output Parameters

w, z	<p>REAL for <code>sspevd</code> DOUBLE PRECISION for <code>dspevd</code> Arrays: $w(*)$, DIMENSION at least $\max(1, n)$. If $info = 0$, contains the eigenvalues of the matrix A in ascending order. See also $info$. $z(ldz,*)$. The second dimension of z must be: at least 1 if $jobz = 'N'$; at least $\max(1, n)$ if $jobz = 'V'$. If $jobz = 'V'$, then this array is overwritten by the orthogonal matrix z which contains the eigenvectors of A. If $jobz = 'N'$, then z is not referenced.</p>
ap	<p>On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of A.</p>
$work(1)$	<p>On exit, if $info = 0$, then $work(1)$ returns the required $lwork$.</p>
$iwork(1)$	<p>On exit, if $info = 0$, then $iwork(1)$ returns the required $liwork$.</p>
$info$	<p>INTEGER. If $info = 0$, the execution is successful. If $info = i$, then the algorithm failed to converge; i indicates the number of elements of an intermediate tridiagonal form which did not converge to zero. If $info = -i$, the i-th parameter had an illegal value.</p>

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spevd` interface are the following:

<code>ap</code>	Holds the array A of size $(n*(n+1)/2)$.
<code>w</code>	Holds the vector with the number of elements n .
<code>z</code>	Holds the matrix Z of size (n, n) .
<code>uplo</code>	Must be 'U' or 'L'. The default value is 'U'.
<code>jobz</code>	Restored based on the presence of the argument z as follows: $jobz = 'V'$, if z is present, $jobz = 'N'$, if z is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T+E$ such that $\|E\|_2 = O(\epsilon) * \|T\|_2$, where ϵ is the machine precision.

If it is not clear how much workspace to supply, use a generous value of `lwork` (or `liwork`) for the first run or set `lwork = -1` (`liwork = -1`).

If `lwork` (or `liwork`) has any of admissible sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`) on exit. Use this value (`work(1)`, `iwork(1)`) for subsequent runs.

If `lwork = -1` (`liwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`). This operation is called a workspace query.

Note that if `lwork` (`liwork`) is less than the minimal required value and is not equal to -1, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The complex analogue of this routine is [?hpevd](#).

See also [?syevd](#) for matrices held in full storage, and [?sbevd](#) for banded matrices.

?hpevd

Uses divide and conquer algorithm to compute all eigenvalues and (optionally) all eigenvectors of a complex Hermitian matrix held in packed storage.

Syntax

FORTRAN 77:

```
call chpevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, rwork, lrwork, iwork,
liwork, info)
```

```
call zhpevd(jobz, uplo, n, ap, w, z, ldz, work, lwork, rwork, lrwork, iwork,
liwork, info)
```

Fortran 95:

```
call hpevd(ap, w [,uplo] [,z] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all the eigenvalues, and optionally all the eigenvectors, of a complex Hermitian matrix A (held in packed storage). In other words, it can compute the spectral factorization of A as: $A = Z \Lambda Z^H$.

Here Λ is a real diagonal matrix whose diagonal elements are the eigenvalues λ_i , and Z is the (complex) unitary matrix whose columns are the eigenvectors z_i . Thus,

$$A z_i = \lambda_i z_i \text{ for } i = 1, 2, \dots, n.$$

If the eigenvectors are requested, then this routine uses a divide and conquer algorithm to compute eigenvalues and eigenvectors. However, if only eigenvalues are required, then it uses the Pal-Walker-Kahan variant of the QL or QR algorithm.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
-------------	--

uplo CHARACTER*1. Must be 'U' or 'L'.
 If *uplo* = 'U', *ap* stores the packed upper triangular part of *A*.
 If *uplo* = 'L', *ap* stores the packed lower triangular part of *A*.

n INTEGER. The order of the matrix *A* ($n \geq 0$).

ap, work COMPLEX for *chpevd*
 DOUBLE COMPLEX for *zhpevd*
 Arrays:
ap(*) contains the packed upper or lower triangle of Hermitian matrix *A*, as specified by *uplo*.
 The dimension of *ap* must be at least $\max(1, n*(n+1)/2)$.
work is a workspace array, its dimension $\max(1, lwork)$.

ldz INTEGER. The leading dimension of the output array *z*.
 Constraints:
 if *jobz* = 'N', then $ldz \geq 1$;
 if *jobz* = 'V', then $ldz \geq \max(1, n)$.

lwork INTEGER.
 The dimension of the array *work*.
 Constraints:
 if $n \leq 1$, then $lwork \geq 1$;
 if *jobz* = 'N' and $n > 1$, then $lwork \geq n$;
 if *jobz* = 'V' and $n > 1$, then $lwork \geq 2*n$.
 If *lwork* = -1, then a workspace query is assumed; the routine only calculates the optimal size of the *work*, *rwork* and *iwork* arrays, returns these values as the first entries of the *work*, *rwork* and *iwork* arrays, and no error message related to *lwork* or *lrwork* or *liwork* is issued by [xerbla](#). See *Application Notes* for details.

rwork REAL for *chpevd*
 DOUBLE PRECISION for *zhpevd*
 Workspace array, its dimension $\max(1, lrwork)$.

lrwork INTEGER.
 The dimension of the array *rwork*. Constraints:
 if $n \leq 1$, then $lrwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $lwork \geq n$;
 if $jobz = 'V'$ and $n > 1$, then $lwork \geq 2*n^2 + 5*n + 1$.

If $lwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by `xerbla`. See *Application Notes* for details.

$iwork$

INTEGER. Workspace array, its dimension $\max(1, liwork)$.

$liwork$

INTEGER.

The dimension of the array $iwork$.

Constraints:

if $n \leq 1$, then $liwork \geq 1$;

if $jobz = 'N'$ and $n > 1$, then $liwork \geq 1$;

if $jobz = 'V'$ and $n > 1$, then $liwork \geq 5*n+3$.

If $liwork = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $work$, $rwork$ and $iwork$ arrays, returns these values as the first entries of the $work$, $rwork$ and $iwork$ arrays, and no error message related to $lwork$ or $lrwork$ or $liwork$ is issued by `xerbla`. See *Application Notes* for details.

Output Parameters

w

REAL for `chpevd`

DOUBLE PRECISION for `zhpevd`

Array, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the eigenvalues of the matrix A in ascending order. See also $info$.

z

COMPLEX for `chpevd`

DOUBLE COMPLEX for `zhpevd`

Array, DIMENSION ($ldz, *$).

The second dimension of z must be:

at least 1 if $jobz = 'N'$;

at least $\max(1, n)$ if $jobz = 'V'$.

	If <i>jobz</i> = 'V', then this array is overwritten by the unitary matrix <i>Z</i> which contains the eigenvectors of <i>A</i> . If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>ap</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of <i>A</i> .
<i>work</i> (1)	On exit, if <i>info</i> = 0, then <i>work</i> (1) returns the required minimal size of <i>lwork</i> .
<i>rwork</i> (1)	On exit, if <i>info</i> = 0, then <i>rwork</i> (1) returns the required minimal size of <i>lrwork</i> .
<i>iwork</i> (1)	On exit, if <i>info</i> = 0, then <i>iwork</i> (1) returns the required minimal size of <i>liwork</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = <i>i</i> , then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpevd` interface are the following:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

Application Notes

The computed eigenvalues and eigenvectors are exact for a matrix $T + E$ such that $\|E\|_2 = O(\varepsilon) * \|T\|_2$, where ε is the machine precision.

If you are in doubt how much workspace to supply, use a generous value of `lwork` (`liwork` or `lrwork`) for the first run or set `lwork = -1` (`liwork = -1`, `lrwork = -1`).

If you choose the first option and set any of admissible `lwork` (`liwork` or `lrwork`) sizes, which is no less than the minimal value described, the routine completes the task, though probably not so fast as with a recommended workspace, and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`) on exit. Use this value (`work(1)`, `iwork(1)`, `rwork(1)`) for subsequent runs.

If you set `lwork = -1` (`liwork = -1`, `lrwork = -1`), the routine returns immediately and provides the recommended workspace in the first element of the corresponding array (`work`, `iwork`, `rwork`). This operation is called a workspace query.

Note that if you set `lwork` (`liwork`, `lrwork`) to less than the minimal required value and not `-1`, the routine returns immediately with an error exit and does not provide any information on the recommended workspace.

The real analogue of this routine is [?spevd](#).

See also [?heevd](#) for matrices held in full storage, and [?hbevd](#) for banded matrices.

?spevx

Computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix in packed storage.

Syntax

FORTRAN 77:

```
call sspevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz,  
work, iwork, ifail, info)
```

```
call dspevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz,  
work, iwork, ifail, info)
```

Fortran 95:

```
call spevx(ap, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol]
[,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'. If <i>uplo</i> = 'U', <i>ap</i> stores the packed upper triangular part of A . If <i>uplo</i> = 'L', <i>ap</i> stores the packed lower triangular part of A .
<i>n</i>	INTEGER. The order of the matrix A ($n \geq 0$).
<i>ap, work</i>	REAL for <code>sspevx</code> DOUBLE PRECISION for <code>dspevx</code> Arrays: <i>ap</i> (*) contains the packed upper or lower triangle of the symmetric matrix A , as specified by <i>uplo</i> . The dimension of <i>ap</i> must be at least $\max(1, n*(n+1)/2)$.

work()* is a workspace array, DIMENSION at least $\max(1, 8n)$.

vl, vu REAL for *sspevx*
DOUBLE PRECISION for *dspevx*
If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
Constraint: $vl < vu$.
If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu INTEGER.
If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.
If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol REAL for *sspevx*
DOUBLE PRECISION for *dspevx*
The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldz INTEGER. The leading dimension of the output array *z*.
Constraints:
if *jobz* = 'N', then $ldz \geq 1$;
if *jobz* = 'V', then $ldz \geq \max(1, n)$.

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

ap On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of *A*.

m INTEGER. The total number of eigenvalues found,
 $0 \leq m \leq n$. If *range* = 'A', $m = n$, and if *range* = 'I', $m = iu-il+1$.

w, z REAL for *sspevx*
DOUBLE PRECISION for *dspevx*
Arrays:

$w(*)$, DIMENSION at least $\max(1, n)$.

If $info = 0$, contains the selected eigenvalues of the matrix A in ascending order.

$z(ldz,*)$.

The second dimension of z must be at least $\max(1, m)$.

If $jobz = 'V'$, then if $info = 0$, the first m columns of z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of z holding the eigenvector associated with $w(i)$.

If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $ifail$.

If $jobz = 'N'$, then z is not referenced.

Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array z ; if $range = 'V'$, the exact value of m is not known in advance and an upper bound must be used.

ifail

INTEGER.

Array, DIMENSION at least $\max(1, n)$.

If $jobz = 'V'$, then if $info = 0$, the first m elements of $ifail$ are zero; if $info > 0$, the $ifail$ contains the indices the eigenvectors that failed to converge.

If $jobz = 'N'$, then $ifail$ is not referenced.

info

INTEGER.

If $info = 0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, then i eigenvectors failed to converge; their indices are stored in the array $ifail$.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `spevx` interface are the following:

ap Holds the array A of size $(n*(n+1)/2)$.
w Holds the vector with the number of elements n .

<i>z</i>	Holds the matrix <i>z</i> of size (n, n) , where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>v1</i>	Default value for this element is $v1 = -HUGE(v1)$.
<i>vu</i>	Default value for this element is $vu = HUGE(v1)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>v1</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>v1</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>v1</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>v1</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon * \max(|a|, |b|)$, where ϵ is the machine precision.

If *abstol* is less than or equal to zero, then $\epsilon * \|T\|_1$ will be used in its place, where *T* is the tridiagonal matrix obtained by reducing *A* to tridiagonal form. Eigenvalues will be computed most accurately when *abstol* is set to twice the underflow threshold $2 * \text{?lamch('S')}$, not zero.

If this routine returns with *info* > 0, indicating that some eigenvectors did not converge, try setting *abstol* to $2 * \text{?lamch('S')}$.

?hpevx

Computes selected eigenvalues and, optionally, eigenvectors of a Hermitian matrix in packed storage.

Syntax

FORTRAN 77:

```
call chpevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz,
work, rwork, iwork, ifail, info)
```

```
call zhpevx(jobz, range, uplo, n, ap, vl, vu, il, iu, abstol, m, w, z, ldz,
work, rwork, iwork, ifail, info)
```

Fortran 95:

```
call hpevx(ap, w [,uplo] [,z] [,vl] [,vu] [,il] [,iu] [,m] [,ifail] [,abstol]
[,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>job</i> = 'N', then only eigenvalues are computed. If <i>job</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	CHARACTER*1. Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the routine computes all eigenvalues. If <i>range</i> = 'V', the routine computes eigenvalues $\lambda(i)$ in the half-open interval: $vl < \lambda(i) \leq vu$. If <i>range</i> = 'I', the routine computes eigenvalues with indices <i>il</i> to <i>iu</i> .
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.

If *uplo* = 'U', *ap* stores the packed upper triangular part of *A*.
 If *uplo* = 'L', *ap* stores the packed lower triangular part of *A*.

n INTEGER. The order of the matrix *A* ($n \geq 0$).

ap, work COMPLEX for *chpevx*
 DOUBLE COMPLEX for *zhpevx*
 Arrays:
ap(*) contains the packed upper or lower triangle of the Hermitian matrix *A*, as specified by *uplo*.
 The dimension of *ap* must be at least $\max(1, n*(n+1)/2)$.
work(*) is a workspace array, DIMENSION at least $\max(1, 2n)$.

vl, vu REAL for *chpevx*
 DOUBLE PRECISION for *zhpevx*
 If *range* = 'V', the lower and upper bounds of the interval to be searched for eigenvalues.
 Constraint: $vl < vu$.
 If *range* = 'A' or 'I', *vl* and *vu* are not referenced.

il, iu INTEGER.
 If *range* = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned.
 Constraint: $1 \leq il \leq iu \leq n$, if $n > 0$; $il=1$ and $iu=0$ if $n = 0$.
 If *range* = 'A' or 'V', *il* and *iu* are not referenced.

abstol REAL for *chpevx*
 DOUBLE PRECISION for *zhpevx*
 The absolute error tolerance to which each eigenvalue is required. See *Application notes* for details on error tolerance.

ldz INTEGER. The leading dimension of the output array *z*.
 Constraints:
 if *jobz* = 'N', then $ldz \geq 1$;
 if *jobz* = 'V', then $ldz \geq \max(1, n)$.

rwork REAL for *chpevx*
 DOUBLE PRECISION for *zhpevx*
 Workspace array, DIMENSION at least $\max(1, 7n)$.

iwork INTEGER. Workspace array, DIMENSION at least $\max(1, 5n)$.

Output Parameters

ap On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. The elements of the diagonal and the off-diagonal of the tridiagonal matrix overwrite the corresponding elements of *A*.

m INTEGER. The total number of eigenvalues found, $0 \leq m \leq n$.
If *range* = 'A', $m = n$, and if *range* = 'I', $m = iu - il + 1$.

w REAL for *chpevx*
DOUBLE PRECISION for *zhpevx*
Array, DIMENSION at least $\max(1, n)$.
If *info* = 0, contains the selected eigenvalues of the matrix *A* in ascending order.

z COMPLEX for *chpevx*
DOUBLE COMPLEX for *zhpevx*
Array *z*(*ldz*,*).
The second dimension of *z* must be at least $\max(1, m)$.
If *jobz* = 'V', then if *info* = 0, the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix *A* corresponding to the selected eigenvalues, with the *i*-th column of *z* holding the eigenvector associated with $w(i)$.
If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.
If *jobz* = 'N', then *z* is not referenced.
Note: you must ensure that at least $\max(1, m)$ columns are supplied in the array *z*; if *range* = 'V', the exact value of *m* is not known in advance and an upper bound must be used.

ifail INTEGER.
Array, DIMENSION at least $\max(1, n)$.
If *jobz* = 'V', then if *info* = 0, the first *m* elements of *ifail* are zero; if *info* > 0, the *ifail* contains the indices the eigenvectors that failed to converge.
If *jobz* = 'N', then *ifail* is not referenced.

info INTEGER.
 If *info* = 0, the execution is successful.
 If *info* = -*i*, the *i*-th parameter had an illegal value.
 If *info* = *i*, then *i* eigenvectors failed to converge; their indices are stored in the array *ifail*.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine `hpevx` interface are the following:

<i>ap</i>	Holds the array <i>A</i> of size $(n*(n+1)/2)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) , where the values <i>n</i> and <i>m</i> are significant.
<i>ifail</i>	Holds the vector with the number of elements <i>n</i> .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>v1</i>	Default value for this element is $v1 = -HUGE(v1)$.
<i>vu</i>	Default value for this element is $vu = HUGE(v1)$.
<i>il</i>	Default value for this argument is $il = 1$.
<i>iu</i>	Default value for this argument is $iu = n$.
<i>abstol</i>	Default value for this element is $abstol = 0.0_WP$.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: $jobz = 'V'$, if <i>z</i> is present, $jobz = 'N'$, if <i>z</i> is omitted Note that there will be an error condition if <i>ifail</i> is present and <i>z</i> is omitted.
<i>range</i>	Restored based on the presence of arguments <i>v1</i> , <i>vu</i> , <i>il</i> , <i>iu</i> as follows: $range = 'V'$, if one of or both <i>v1</i> and <i>vu</i> are present, $range = 'I'$, if one of or both <i>il</i> and <i>iu</i> are present, $range = 'A'$, if none of <i>v1</i> , <i>vu</i> , <i>il</i> , <i>iu</i> is present, Note that there will be an error condition if one of or both <i>v1</i> and <i>vu</i> are present and at the same time one of or both <i>il</i> and <i>iu</i> are present.

Application Notes

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to $abstol + \epsilon \max(|a|, |b|)$, where ϵ is the machine precision.

If $abstol$ is less than or equal to zero, then $\epsilon * ||T||_1$ will be used in its place, where T is the tridiagonal matrix obtained by reducing A to tridiagonal form. Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 * \text{lamch}('S')$, not zero.

If this routine returns with $info > 0$, indicating that some eigenvectors did not converge, try setting $abstol$ to $2 * \text{lamch}('S')$.

?sbev

Computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix.

Syntax

FORTRAN 77:

```
call ssbev(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, info)
call dsbev(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, info)
```

Fortran 95:

```
call sbev(ab, w [,uplo] [,z] [,info])
```

Description

This routine is declared in `mkl_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mkl_lapack.h` for C interface.

The routine computes all eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A .

Input Parameters

<i>jobz</i>	CHARACTER*1. Must be 'N' or 'V'. If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	CHARACTER*1. Must be 'U' or 'L'.

If *uplo* = 'U', *ab* stores the upper triangular part of *A*.
 If *uplo* = 'L', *ab* stores the lower triangular part of *A*.

n INTEGER. The order of the matrix *A* ($n \geq 0$).

kd INTEGER. The number of super- or sub-diagonals in *A* ($kd \geq 0$).

ab, work REAL for *ssbev*
 DOUBLE PRECISION for *dsbev*.
 Arrays:
ab (*ldab*,*) is an array containing either upper or lower triangular part of the symmetric matrix *A* (as specified by *uplo*) in band storage format.
 The second dimension of *ab* must be at least $\max(1, n)$.
work (*) is a workspace array.
 The dimension of *work* must be at least $\max(1, 3n-2)$.

ldab INTEGER. The leading dimension of *ab*; must be at least $kd + 1$.

ldz INTEGER. The leading dimension of the output array *z*.
 Constraints:
 if *jobz* = 'N', then $ldz \geq 1$;
 if *jobz* = 'V', then $ldz \geq \max(1, n)$.

Output Parameters

w, z REAL for *ssbev*
 DOUBLE PRECISION for *dsbev*
 Arrays:
w (*), DIMENSION at least $\max(1, n)$.
 If *info* = 0, contains the eigenvalues of the matrix *A* in ascending order.
z (*ldz*,*).
 The second dimension of *z* must be at least $\max(1, n)$.
 If *jobz* = 'V', then if *info* = 0, *z* contains the orthonormal eigenvectors of the matrix *A*, with the *i*-th column of *z* holding the eigenvector associated with *w*(*i*).
 If *jobz* = 'N', then *z* is not referenced.

<i>ab</i>	On exit, this array is overwritten by the values generated during the reduction to tridiagonal form. If <i>uplo</i> = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix <i>T</i> are returned in rows <i>kd</i> and <i>kd+1</i> of <i>ab</i> , and if <i>uplo</i> = 'L', the diagonal and first subdiagonal of <i>T</i> are returned in the first two rows of <i>ab</i> .
<i>info</i>	INTEGER. If <i>info</i> = 0, the execution is successful. If <i>info</i> = - <i>i</i> , the <i>i</i> -th parameter had an illegal value. If <i>info</i> = <i>i</i> , then the algorithm failed to converge; <i>i</i> indicates the number of elements of an intermediate tridiagonal form which did not converge to zero.

Fortran 95 Interface Notes

Routines in Fortran 95 interface have fewer arguments in the calling sequence than their FORTRAN 77 counterparts. For general conventions applied to skip redundant or restorable arguments, see [Fortran 95 Interface Conventions](#).

Specific details for the routine *sbev* interface are the following:

<i>ab</i>	Holds the array <i>A</i> of size $(kd+1, n)$.
<i>w</i>	Holds the vector with the number of elements <i>n</i> .
<i>z</i>	Holds the matrix <i>Z</i> of size (n, n) .
<i>uplo</i>	Must be 'U' or 'L'. The default value is 'U'.
<i>jobz</i>	Restored based on the presence of the argument <i>z</i> as follows: <i>jobz</i> = 'V', if <i>z</i> is present, <i>jobz</i> = 'N', if <i>z</i> is omitted.

?hbev

Computes all eigenvalues and, optionally, eigenvectors of a Hermitian band matrix.

Syntax

FORTRAN 77:

```
call chbev(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, rwork, info)
call zhbev(jobz, uplo, n, kd, ab, ldab, w, z, ldz, work, rwork, info)
```

Fortran 95:

```
call hbev(ab, w [,uplo] [,z] [,info])
```

Description

This routine is declared in `mk1_lapack.fi` for FORTRAN 77 interface, in `lapack.f90` for Fortran 95 interface, and in `mk1_lapack.h` for C interface.

The routine computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A .

Input Parameters
