

Tendencies of PMS research in Brazil

Jacques Lépine, IAG-USP

Some important historical steps

- **1989- TW Hya** de la Reza, Torres, Quast, Castilho, Vieira (ApJ 343 L61) called attention on puzzling existence of T Tauri stars far from any molecular cloud. TW Hya was a prototype.

- **started 1990 - The PDS (Pico dos Dias) survey**

Previous surveys for new T Tauri stars always searched around known star forming regions (Orion, ρ Oph, etc).

PDS is the first large-scale unbiased survey

Method:

- use known T Tauri stars to verify the typical **IRAS colors [12-25] and [25-60]**
- select in IRAS catalog all objects within this range of color. **850 objects** found.
- verify if the IRAS source has an optical counterpart, with magnitude 13 or brighter (Guide Star Catalog), remove galaxies, planetary nebulae, etc.
- take spectra of objects in the 655-673 nm range, which includes H α and resonant Li I line

First PDS results: Gregorio-Hetem, Lépine, Quast, Torres, de la Reza (1992 AJ)
Torres, Quast, de la Reza, Gregorio-Hetem, Lépine (1995 AJ)

150 stars observed, 50 new T Tauri, 37 new AeBe

30 previously known observed, photometry and spectroscopy of all objects,
and many interesting parallel results: Li-rich giants, 1 quasar, FU Ori-like, etc

After PDS

Stellar groups and associations, dynamics of star forming regions, connection with molecular clouds. Question: what triggers star formation? how star formation propagates?

T Tauri stars and AeBe: circumstellar structure, disks, binaries, spectral energy distribution, variability. Questions: how to classify PMS objects, how do the disk and the star evolve during PMS phase?

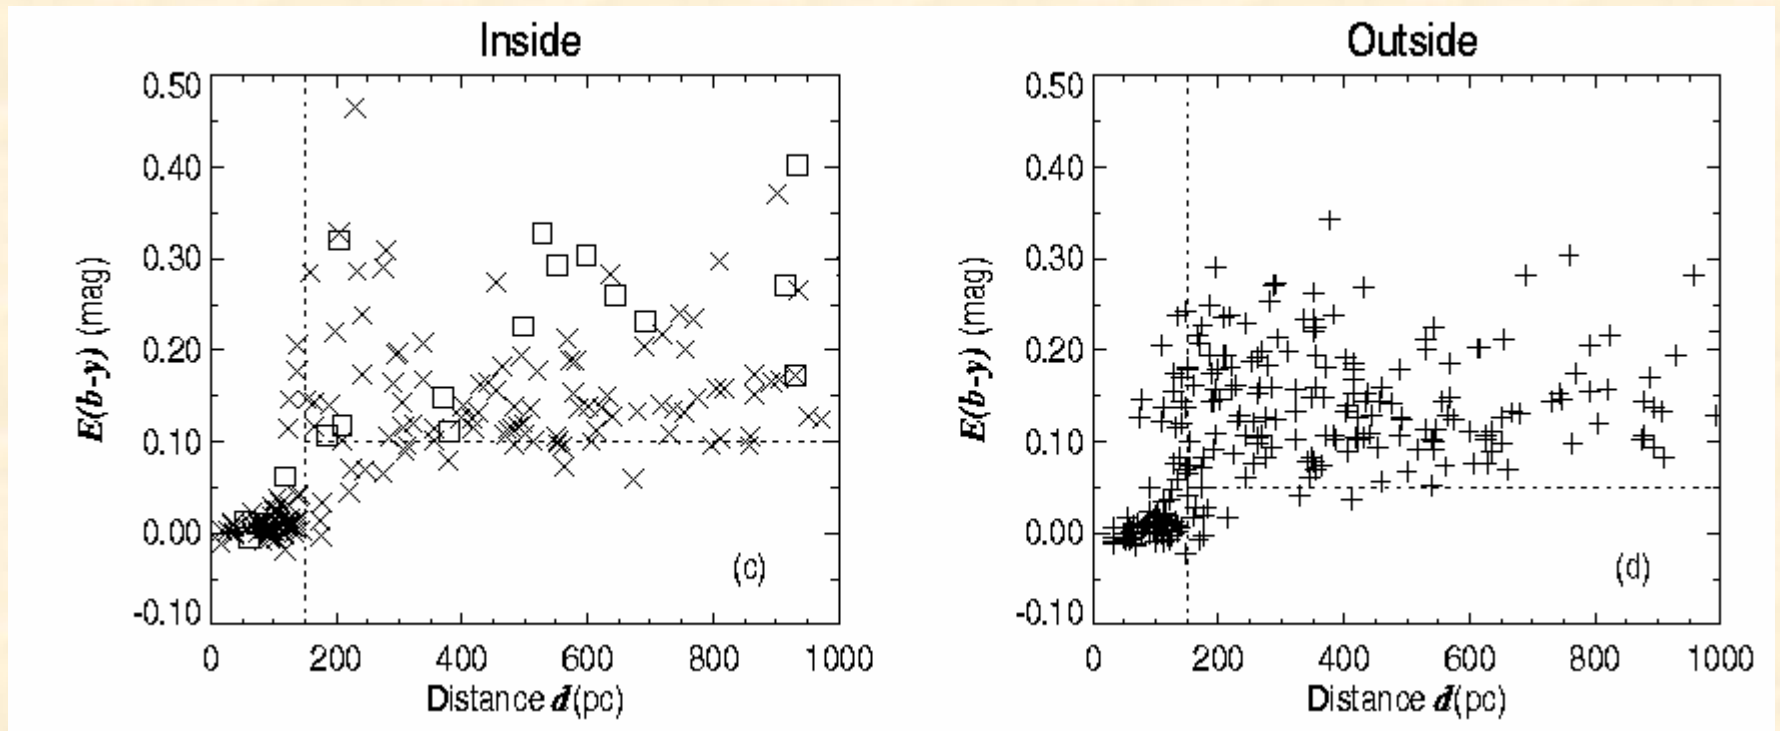

metallicity abundance, rotation

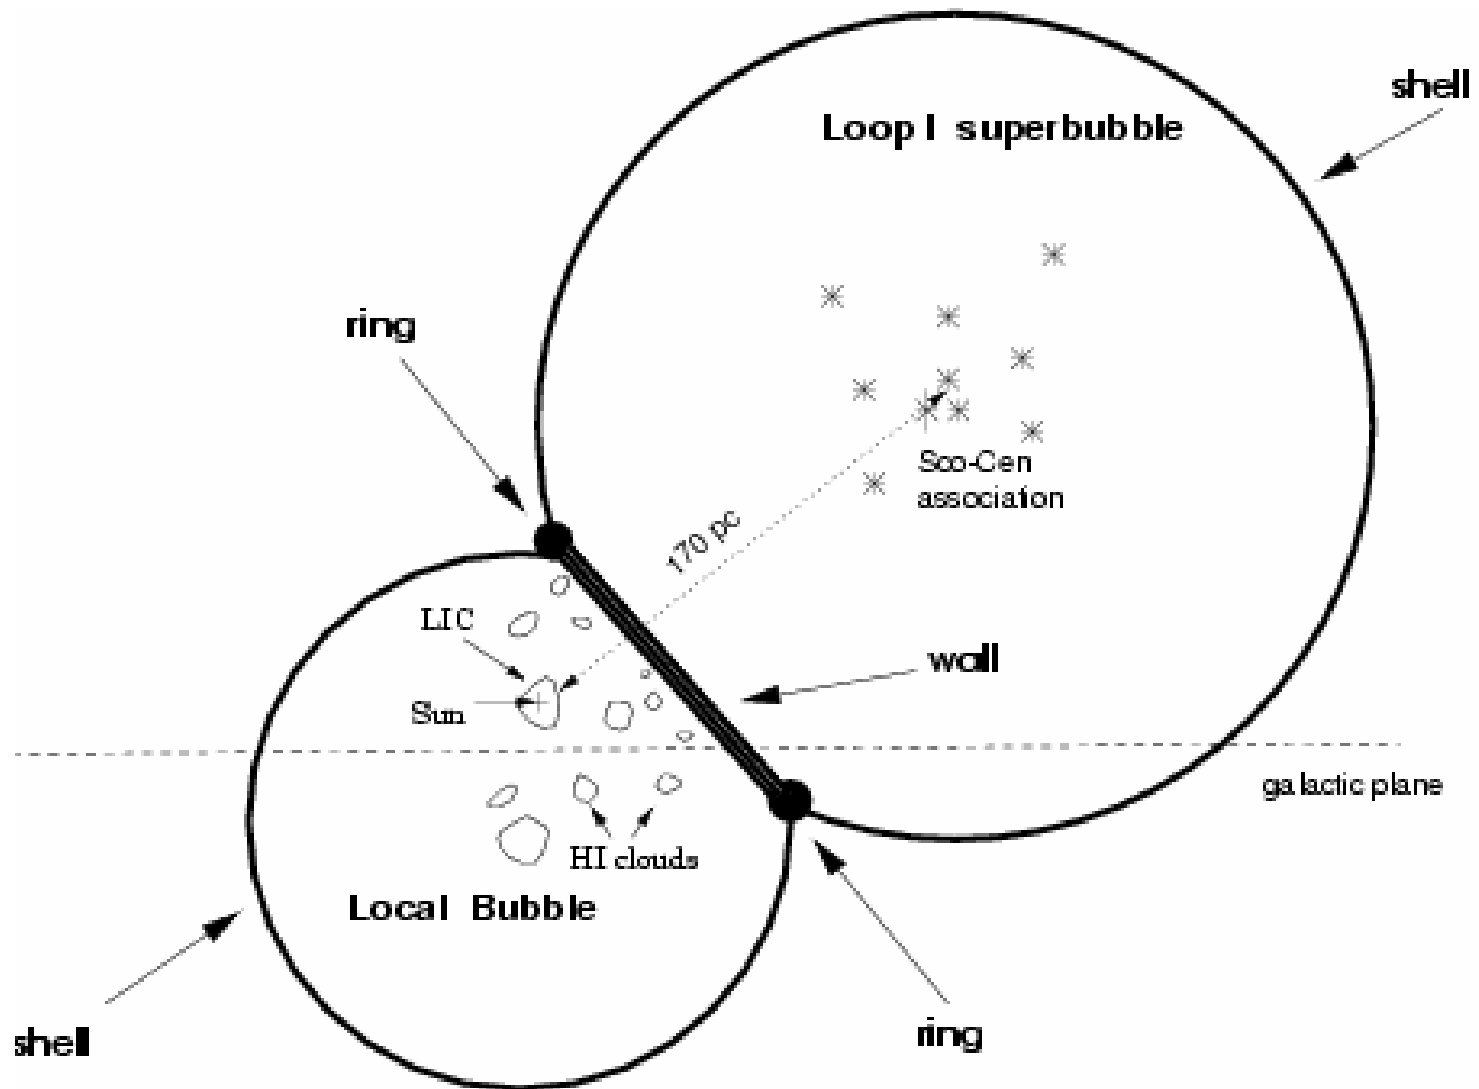

**Connections
with IM,
large-scale SF**

Connections with interstellar medium

**Filaments connecting the galactic plane
to the rho Oph –Sco-Cen groups of young stars**

Fig. 1. Stars of the ρ Oph region, and members of the OB associations listed by de Geus et al. (1991); crosses: Upper Scorpius; open stars: Taurus; filled stars: Lower Centaurus

HVC impact model Lépine & Duvert 1994

ment, concerns the nature of the Monoceros R2 cloud, at about $l = 215^\circ$, $b = -12^\circ$. It seems unlikely that this cloud formed independently from the rest of the complex; it is probably the far edge of the shocked layer, situated at about 620 pc from us.

The main differences between our model of the formation of the OMC and that of Franco et al. are the following: 1) we consider that the HVC arrived from the northern side of the Galaxy, and that we are observing a primary collision. An argument in favor of our view is that a collision strongly distorts the gas distribution, so that in a secondary collision the incident gas cannot be regarded as having a simple geometry. In the case of a secondary collision we would expect to observe clusters of stars formed in the first collision, as discussed later in the case of the

would not be surprising to find cloud complexes looking like cylinders with a hole at their top, because the gas of the center of the shocked layer can dissipate sooner than at other places. Such structures, seen almost edge-on, might look like a ring of smoke. We argue later in this work that this is the case for the Taurus-Auriga-Perseus complex.

3.2. The ρ Oph region

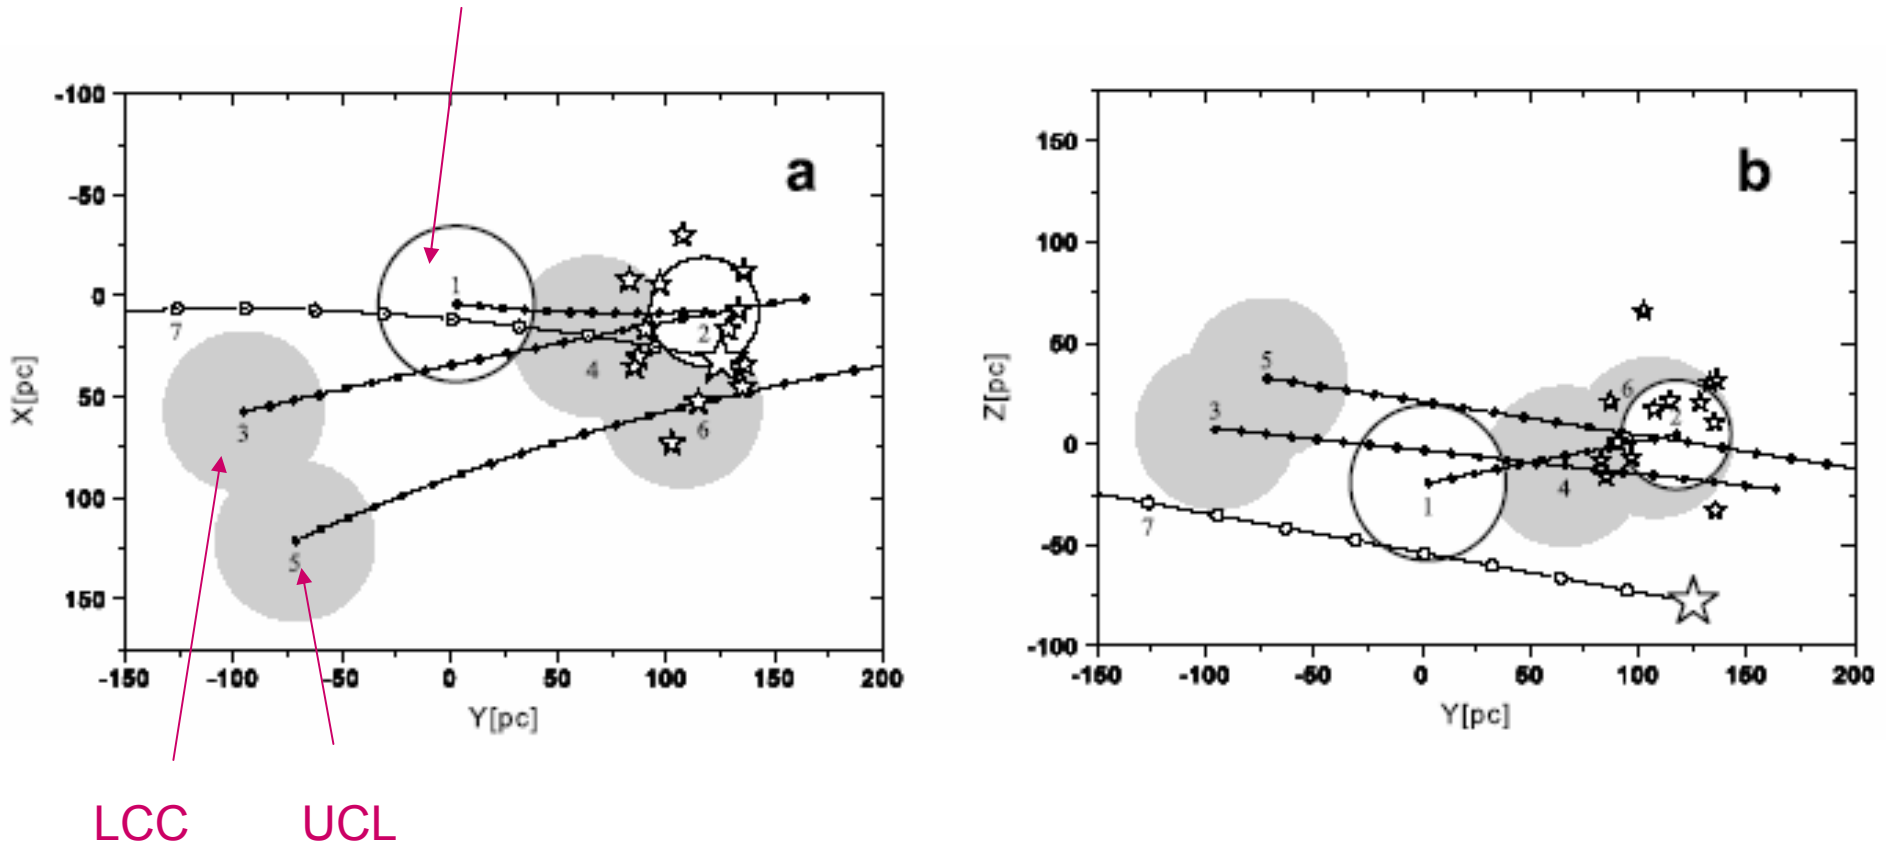

The filamentary complex of dark clouds in Ophiuchus extend over a region of about 15° by 15° . While the first CO and star-counts studies concentrated on the ρ Oph cloud, which is the densest core in the westernmost part of the complex, maps of the whole region are now available, including the northern filaments

incorrect like many others

Sartori, Lépine, Dias

Beta Pictoris moving group

Ortega, de la Reza, Jilinski, and B. Bazzanella (2004) : the groups shown were close together some 13 My ago . They interpret in terms of supernova explosion

Torres and collaborators are identifying many **moving groups of young stars**

start from ROSAT list of X-ray candidates, use Tycho proper motions,
and precise radial velocities obtained with FEROS spectrograph
select young stars based on Li line

6- dimensional analysis : X, Y, Z, U, V, W

Useful results for COROT

- every young star belongs to a moving group or association.
- when PMS targets are selected, we can identify to which moving it belongs, and provide precise age determination . Better understanding of variability type.

INVESTIGATION OF 131 HERBIG Ae/Be CANDIDATE STARS¹

S. L. A. VIEIRA,² W. J. B. CORRADI,² S. H. P. ALENCAR,^{2,3} L. T. S. MENDES,²
C. A. O. TORRES,⁴ G. R. QUAST,⁴ M. M. GUIMARÃES,² AND L. DA SILVA⁵

Received 2002 August 19; accepted 2003 August 29

Eclipses by circumstellar material in the T Tauri star AA Tau

II. Evidence for non-stationary magnetospheric accretion*

J. Bouvier¹, K. N. Grankin², S. H. P. Alencar³, C. Dougados¹, M. Fernández⁴, G. Basri⁵, C. Batalha⁶, E. Guenther⁷,
M. A. Ibrahimov², T. Y. Magakian⁸, S. Y. Melnikov², P. P. Petrov⁹, M. V. Rud¹⁰, and M. R. Zapatero Osorio¹¹

variability of AA Tau is interpreted as occultation of the stellar photosphere by circumstellar material orbiting the star at keplerian velocity.

The pre-main sequence spectroscopic binary AK Scorpii revisited^{★,★★}

S. H. P. Alencar^{1,6}, C. H. F. Melo², C. P. Dullemond³, J. Andersen⁴, C. Batalha⁵, L. P. R. Vaz¹, and R. D. Mathieu⁷

VARIABILITY OF SOUTHERN T TAURI STARS. II. THE SPECTRAL VARIABILITY OF THE CLASSICAL T TAURI STAR TW HYDRAE¹

SILVIA H. P. ALENCAR² AND CELSO BATALHA³

Received 2001 October 16; accepted 2002 January 28

They found periodic variability in the veiling, line profile intensities. It seems that accretion and outflow are related. Blue Halpa absorption is more intense when accretion rate is larger.
